## ACKNOWLEDGMENTS

Kristina Ramstad and Megan McPhee collected scales and took length and weight measurements at King Cove and Brenda Rogers aged the scales and examined for scale holes. Thanks also to Arnie Shaul, Charlie Swanton, Bev Cross and Jim Miller of the Alaska Department of Fish and Game for providing preliminary 1995 catch and escapement statistics.

This project was funded jointly by Peter Pan Seafoods, Trident Seafoods, Icicle Seafoods, and Crusader (through Pacific Seafood Processors Association), the Aleutian East Borough, and Concerned Area M Fishermen.

## KEY WORDS

sockeye salmon, chum salmon, False Pass, Bristol Bay, Arctic-Yukon-Kuskokwim

## INTRODUCTION

The salmon fisheries on the south side of the Alaska Peninsula have been the subject of controversy since nearly the time of their inception in the early 1900s. The June fisheries in the Shumagin Islands and south of Unimak Island, which are collectively called the False Pass fishery or South Peninsula June fishery, target on non-local sockeye (Oncorhynchus nerka) salmon. Several studies, culminating in a 1987 tagging experiment by the Alaska Department of Fish and Game (ADFG), have clearly demonstrated that most of the sockeye salmon caught in the False Pass fishery ( $\sim 80 \%$ ) are bound for rivers in Bristol Bay (Eggers et al. 1991, Rogers 1990). The non-Bristol Bay contributions to the sockeye salmon catches in 1987 were mainly North Peninsula stocks (7\%) in the South Unimak catch and stocks from Chignik (20\%), North Peninsula (10\%) and Kodiak (9\%) in the Shumagin catch. For management purposes, ADFG has assumed that the entire False Pass sockeye salmon catch consists of Bristol Bay fish. Since 1975, the annual False Pass sockeye salmon catch has been based on a quota (guideline harvest) of $8.3 \%$ (Unimak, $6.8 \%$ and Shumagin, $1.5 \%$ ) of the forecasted Bristol Bay and False Pass catch (McCullough et al. 1995). The average annual percent of the total Bristol Bay catch taken in the False Pass fishery over the past 10 years was $5.2 \%$ (range: $2.9-7.3 \%$ ). The fishery has, thus, been managed in a very conservative manner, especially considering the historical high abundance of sockeye salmon over the past 10 years; however, the fishery is not without controversy because with the increase in sockeye salmon catch there was an increase in the catch of non-local chum ( $O$. keta) salmon.

The 1987 tagging of chum salmon demonstrated that while Bristol Bay stocks still contributed the highest percentage to the False Pass catch (Unimak, 40\%; Shumagin, 18\%; and combined 38\%), Asian stocks were the next major contributor in 1987 (Unimak 18\%; Shumagin 39\%; and combined $20 \%$ ). Arctic and Yukon River stocks, for which there had been conservation concerns, were minor contributors to the 1987 False Pass chum salmon catch. However, it was argued to the Alaska Board of Fisheries that these northern stocks were in low abundance in 1987 and that their typical contribution to the False Pass catch was underestimated by the 1987 tagging. The fishery has operated with a chum salmon cap (second quota) since 1986 (with an exception in 1987) and the sockeye-targeted fishery has been closed early three times (1986, 1988, and 1991) because the chum cap was attained (McCullough et al. 1995). The resultant loss in sockeye salmon catch to the False Pass fishery for those 3 years was 1.8 million fish, while the gain to the coastal runs of chum salmon to the Arctic and Yukon areas was largely unmeasurable.

The potential impact of the False Pass fishery on a single stock or group of stocks will depend on the availability of the stock (the proportion migrating through the fishery) and the relative abundance of that stock and other contributing stocks; both are likely to vary from year to year. Our main purpose is to examine the year-to-year changes in chum salmon abundance with particular reference to (1) the abundance in 1987 and (2) a possible increase in the contribution of Asian chum salmon. In recent years, False Pass fishermen have noted a significant occurrence of chum salmon with a snake-like appearance. These chum salmon of poor condition (low weight for their length) are believed to originate from Japanese hatcheries, because Japan has increased production to the point of density-dependent growth. The occurrence of Asian chum salmon in the False Pass fishery may also be assessed from the presence of scale holes (focal scale resorbtion)
that are nearly unique to Asian stocks, both hatchery and wild (Bigler 1988 and 1989). The specific objectives of our work in 1995 were to (1) update estimates of chum salmon runs (catch and escapement) to North Pacific coastal regions, (2) measure the incidence of scale holes in the 1995 False Pass catch, and (3) examine frequency distributions of chum salmon condition factors from the 1995 catch.

## METHODS

The accuracy of estimates of the annual runs (catch and escapement) of sockeye and chum salmon to major North Pacific regions is quite variable. Annual catch statistics for sockeye and chum salmon since the 1950s are fairly accurate (probably within 10\%) for most North American regions and Japan, but less so for Russia (Fredin 1980). There are accurate annual escapement estimates for sockeye salmon for most runs since the mid-1950s, but estimates for chum salmon escapements are either lacking, inaccurate, or only available for recent years. For most regions of Alaska, except the Arctic-Yukon-Kuskokwim (A-Y-K), chum salmon runs coincide with more valuable sockeye or more numerous pink (O. gorbuscha) salmon runs and therefore receive less monitoring for escapement. However, chum salmon runs can be estimated in these situations from the chum salmon catch and the rate of exploitation on the targeted species (Rogers 1987). The most important statistics for management are usually the most recent statistics, and these are only available in preliminary form or in-house reports. This report relies heavily on 1995 catch and escapement statistics provided by ADFG area management biologists in fall 1995.
Annual runs of chum salmon to North Pacific regions from 1970 to 1994 were estimated primarily from catch and escapement statistics that were presented in Rogers (1995). Sockeye salmon exploitation rates were utilized in Bristol Bay even though some aerial and sonar estimates of chum salmon escapement were available (Nushagak and Togiak). Sonar estimates of chum salmon escapement were available for a few recent years in the Yukon River and regressions of sonar count on spawning survey count were used to estimate escapements in years when only spawning survey counts were available (Rogers 1994). Expanded aerial survey and weir counts from selected spawning areas were used to estimate escapements in the Kotzebue, Norton Sound, and Kuskokwim regions. Aerial survey estimates were used for most estimates of chum salmon escapements to central Alaska; otherwise, assumed exploitation rates and chum salmon catches were used to estimate chum salmon runs.

Chum salmon from the 1995 False Pass catches (June 13-30) were sampled at the Peter Pan processing plant in King Cove. Fish were selected randomly from the processing line and measured for length (mid-eye to tail fork) and weight. Sex was determined from external appearance, and two scales were collected from the preferred region. Chum without scales in the preferred region were not included in the samples; these chum were usually the smaller fish. The first samples were collected from the June 16 catches and the last samples collected from the June 28 catches. Data from the field forms (date, location, scale card number, fish number, sex, length, and weight) were entered on to a computer file. Weights measured in pounds and ounces were transformed to kilograms.

Scales were aged and examined for focal scale resorbtion (holes) by an experienced scale reader who had been tutored by Mr. Brian Bigler (Wards Cove Packing Co., Seattle, Washington) on the identification of focal scale resorbtion. Ages and occurrences of scale holes were then added to the computer database. Data were stratified by location (South Unimak and Shumagin Is.), date, sex, and age. Weight-length scattergrams were examined for outliers, which were then removed prior to statistical analyses (e.g., means and standard deviations of lengths and weights, age compositions, and length-weight regressions). A condition factor was calculated from weight in grams divided by the cube of length in centimeters. Frequency distributions of condition factors were then graphed and examined for possible bimodality.

Catch statistics for the False Pass fisheries of past years were obtained from McCullough et al. (1995). Mr. A.R. Shaul (ADFG, Kodiak, Alaska) provided preliminary catches by gear, area, and date for 1995. These preliminary catches were used to weight stratified means (length, weight, age compositions) to obtain the annual means for 1995.

## RESULTS

## ABUNDANCE

Most sockeye salmon caught in the False Pass area during June are bound for Bristol Bay, and this fact was used by Eggers and Shaul (1987) to develop an in-season forecast $\sim 10$ days prior to the arrival of the fish in Bristol Bay (Fig. 1). I updated the database used by Eggers and Shaul (Table 1), added it to their database, and calculated a new regression to predict the western Alaska (Bristol Bay, North Peninsula, and Kuskokwim) run (Fig. 2). Sockeye salmon were difficult to catch in 1990, 1994, and again in 1995, probably because there were persistent offshore winds, so there was a low CPUE relative to the run. Omitting the 1990, 1994, and 1995 observations as outliers, the CPUE of sockeye salmon at South Unimak explained $58 \%$ of the annual variation in the western Alaska runs. This correlation is very good considering that the majority of Bristol Bay sockeye do not pass through the Shumagin Islands and south of Unimak Island on their homeward migration (Rogers 1987). The age composition of the sockeye salmon catch at False Pass has also been useful in forecasting the Bristol Bay runs (Table 2). In contrast, the chum salmon catches at False Pass have shown no correlation with the chum salmon runs to western Alaska even though these stocks were the most abundant stocks in the 1987 tagging (Fig. 2). Chum salmon abundance in the 1990s has changed relative to 1987 as follows: decreased for Bristol Bay/North Peninsula; about the same for the A-Y-K region (except 1995); and increased for Asian (primarily Japanese hatchery) stocks.

The species compositions (sockeye and chum salmon only) in the False Pass catches and the western Alaska runs have shown some correlation that has changed over the years along with an increase in the production from Japanese hatcheries (Table 3 and Fig. 3). The chum salmon percentage in the False Pass catch of 1995 was a little below average as was the chum salmon percentage in Western Alaska. Both runs were exceptionally large in 1995. Sockeye salmon abundance in 1995 was the highest in history while Bering Sea runs of chum salmon were the
fourth highest. The Japanese hatchery returns were the highest on record and total chum abundance was second largest on record (Tables 4-7). The impact of Japanese chum salmon on the False Pass fishery is evident in the correlation between the differences in chum salmon percentages between False Pass and Western Alaska as a function of the Japanese catch (hatchery return). The Japanese chum salmon catch explained $52 \%$ of the annual variation in the differences in False Pass and western Alaska chum salmon percentages (Fig. 3). With increases in Japanese hatchery chum salmon, the False Pass catches have contained a higher percentage of chum salmon than expected from the percentages of chum salmon in the Western Alaska runs.

One would expect the annual catch of chum salmon in the False Pass fishery to be somewhat correlated with the catch of the more abundant and targeted sockeye salmon, and this was so until the imposition of chum salmon caps on the fishery. For the years with a chum salmon cap, there has been no significant correlation between sockeye and chum salmon catches. A regression of False Pass chum salmon catch on the False Pass sockeye catch as a proportion of the Bristol Bay run has been used to predict the chum salmon catch given the sockeye salmon quota and Bristol Bay run (Eggers 1993). Although there was a significant correlation for all years since 1977, there was no correlation when only years with a chum salmon cap were considered. Assuming there is a chum salmon cap for 1996 , there is at present no statistically significant relationship to predict the chum salmon catch given the sockeye quota and forecast for 1996.

## Age, Weight, AND LENGTH

About $94 \%$ of the chum salmon caught in the 1995 South Unimak and Shumagin fisheries were ages 0.3 and 0.4 ; however, there were higher percentages of both older (age 0.5 and 0.6 ) and younger (age 0.2) chum salmon in 1995 than in past years (Table 8). Chum salmon in 1995 were larger than in past years but condition factors were similar to 1994. The False Pass chums in 1995 were again much larger at each age than the average chum salmon in the Nushagak (Bristol Bay) catch (Table 9).

In the Nushagak catch, annual mean lengths of 3-ocean chum salmon and 3-ocean sockeye salmon have been significantly correlated (1967-1995, $\mathrm{r}=0.81$ ). Nushagak and other Bristol Bay sockeye have been smaller than average since the consecutive large runs that began in 1989 (Fig. 4). The annual sizes of Bristol Bay sockeye are density dependent (large numbers/small size) and temperature dependent (cold spring/small size), and for recent years the small size has also caused some delay in maturation as fish have been spending a longer time at sea (Rogers and Ruggerone 1993). In the Nushagak catch, 3-ocean chum salmon tend to be shorter and lighter than 3-ocean sockeye salmon; however, annual mean lengths of chums were more closely correlated with the numbers of sockeye in the western Alaska runs ( $\mathrm{r}=.77$ ) than were the mean lengths of Nushagak sockeye ( r $=.75$ ). There was no significant correlation between chum salmon mean lengths and Nushagak chum or sockeye runs (Table 9). Chum and sockeye salmon returning to Bristol Bay over the past 7 years would likely have been even smaller if the spring weather since 1989 had not been warmer than normal (Fig. 5). Early Bristol Bay runs have been associated with warm spring weather and
late runs with cold spring weather; however, the late run in 1994 was associated with average spring temperatures.

## FOCAL SCALE RESORBTION

Murphy (1993) presented a summary of the incidence of focal scale resorbtion for chum salmon in the False Pass fisheries, including our preliminary results for 1992. Scales had only been examined from South Unimak in 1990 (600) and from the Shumagins in 1989 (302) and 1990 (298). The final results for 1995 are given in Table 10. For the combined samples, 1.15\% of the 1992 chum salmon, $1.53 \%$ of 1993 , and $2.25 \%$ of 1994 had scale "holes." Thus, the 1995 samples with a combined percentage of $1.78 \%$ was typical of the past 2 years.
Assuming that the incidence of focal scale resorbtion is zero in Alaskan stocks and $\sim 11.8 \%$ in Asian stocks (Murphy 1993), the Asian stock contribution has been close to the estimated $20 \%$ from the 1987 tagging. To obtain more precise estimates of Asian stock contribution, we need a measure of the year-to-year variation in the incidence in Asian stocks. From the tagging results in 1987, we would expect the incidence of "holes" to be much greater in the Shumagin samples than in the South Unimak samples, and this has been the case for the past 3 years.

## DISCUSSION

The catch of chum salmon in the 1995 False Pass fisheries $(520,000)$ was well below the chum salmon cap of 700,000 and, even though there was a near record sockeye salmon run to Bristol Bay of 61 million, the False Pass fisheries could only catch about 1.6 million (less than half of the pre-season quota). In a normal year, $\sim 25 \%$ of maturing Bristol Bay sockeye return from the central and eastern Gulf of Alaska, and many of these pass through the Shumagin and South Unimak fishing districts (Rogers 1987). In 1990, 1994 and again in 1995, a smaller than normal proportion of the Bristol Bay run returned from the Gulf or the sockeye returning from the Gulf migrated farther offshore than normal. The percentage of chum salmon in the catch ( $20 \%$ ) was below average in 1995 but still $40 \%$ above the percentage of chums in western Alaska (14\%). There was a record abundance of Japanese chum and the large runs of chum to other areas; however, as was the case with sockeye, chum were not very available to the False Pass fisheries in 1995. Fishing strategies by ADFG management and the False Pass fishermen to avoid areas and times of high chum salmon abundance have helped reduce catches of chum salmon in recent years; however, this has also made chum salmon catches and CPUE useless in forecasting either the abundance of chums in next year's False Pass catch or in the western Alaska runs.

Western Alaska includes Bristol Bay, North Peninsula and $85 \%$ of South Peninsula catch.
Japan high seas catches since1992 are included in Russian run.

Table 7. North Pacific runs of chum salmon, 1970-1995, catch and escapement (in millions).

Western Alaska includes Bristol Bay, North Peninsula and the Yukon-Kuskokwim region.
Japan coastal run does not include hatchery returns (brood stock) to Hokkaido and Honshu.
Japan high seas catches since 1992 included in Russian runs.

Table 8. Summary of length, weight and condition factors for chum salmon in the False Pass catches.

Sources: Yuen and Nelson (1984), annual ADF\&G reports on Bristol Bay salmon (e.g., Stratton and Crawford 1992 and B. Cross [ADF\&G] for 1992-1995).
About $55 \%$ of catch in 1994 was with king gear; AWL statistics given for sockeye gear only.
Table 10. Frequencies of focal scale resorption (holes) on chum salmon scales from the 1994 False Pass fisheries.

| Location | Date | Number of normal scales (2) | $\frac{\text { Number }}{\text { One scale }}$ | with holes <br> Both scales | Percent with holes (1 or 2 ) | Number with questionable holes (1 or 2) | Percent with holes including questionable | Number of normal scales (1) | Number with holes | Percent with holes | $\begin{aligned} & \text { Number } \\ & \text { with } \\ & \text { question. } \end{aligned}$ | Percent including question. |
