1. Daily Bristol Bay sockeye salmon runs reconstructed at Port Moller ..... 9
2. Average catches of sockeye salmon at Port Moller stations, June 11-July 5, 1991-96 ..... 10
3. Annual deviations from averages of dates of ice out and summer averages of water temperature, solar radiation, and lake level in Lake Aleknagik ..... 11
4. Annual deviations from averages of phytoplankton and zooplankton densities, water clarity, and conductivity in Lake Aleknagik12

## List of Tables

Table Page

1. Preseason forecasts of Bristol Bay sockeye salmon inshore runs ..... 15
2. Bristol Bay sockeye salmon runs and the predictions from the Port Moller test boat catches ..... 16
3. Mean lengths (mid-eye to tail-fork, mm) of sockeye salmon in the Bristol Bay run ..... 17
4. Average weights of sockeye salmon (lbs) in commercial catches on the east side of Bristol Bay, 1985-96 ..... 18
5. Average weights of sockeye salmon (lbs) in commercial catches on the west sides of Bristol Bay, 1985-96 ..... 19
6. Sockeye salmon escapement (in millions) in excess of management goals for Bristol Bay rivers, 1989-96 ..... 20
7. Cumulative daily escapements of sockeye salmon in the Kvichak and Newhalen rivers, 1991-96 ..... 21
8. The Kvichak lake system escapements and the percentages of fish going to the Newhalen River and Lake Clark ..... 22
9. Age compositions of sockeye salmon on the Kvichak spawning grounds in 1996 ..... 23
10. Estimates of sockeye salmon spawners on 29 spawning grounds in Lake Iliamna and the Newhalen River system ..... 24
11. Mean townet catches and lengths of Sept. 1 of sockeye salmon fry in Lakes Iliamna and Clark ..... 25
12. Summary of 1996 measurements in Lake Aleknagik ..... 26
13. Five-day averages of catches of emergent midges and water temperatures at three stations on Lake Aleknagik, 1996 ..... 27
14. Average catches, lengths, and growth rates for sockeye salmon fry and age 1 threespine stickleback in Lake Aleknagik ..... 28
15. Average townet catches and mean lengths of sockeye salmon fry (by lake area), number of parent spawners, and average catches and mean lengths of threespine stickleback for Lake Nerka ..... 29
16. Occurrence and numbers of juvenile sockeye in stomachs of Arctic char collected by hook and line from Little Togiak River during 30 days after ice-out ..... 30
17. Ground survey counts of sockeye salmon spawners in the Wood River lakes, 1996 ..... 31
18. Age compositions (\%) of sockeye spawners in the Wood River Lakes in 1996 ..... 32
19. Daily counts of sockeye spawners in Hansen Creek, 1996 ..... 33
20. Summary of Hansen Creek spawning surveys, 1990-96 ..... 34

## Acknowledgments

The contribution of graduate student research to our program is vital. In 1996, Alyssa Reischauer and Dan Eastman (Wood River system) and Paul Schlenger, and Frank Leonetti (Kvichak system) completed their MS theses while Troy Hamon, Doug Peterson, and Andrew Hendry conducted their thesis research. Other University of Washington students working on the program in 1996 were Megan McPhee, Kristina Ramstad, Megan Ferguson, Jason Griffith, Cimbal Irwin and Nicholas Kocan (high school student). We especially appreciated the assistance of several volunteers: John Field, Mike Kinnison, Claribel Coronado, and Richard Brocksmith.

This program was supported by the contributions of nine salmon processing companies: Trident Seafoods, Peter Pan Seafoods, Wards Cove Packing, Icicle Seafoods, Nelbro, Ocean Beauty, UniSea, Norquest, and YAK Fisheries.

## INTRODUCTION

Fisheries Research Institute was established in 1946 with the financial support of the major Alaskan salmon (Oncorhynchus spp.) processors to investigate the causes of the declines in production that had occurred in most stocks since the 1930s, work with the government management agency to increase our knowledge of the biology of salmon and the effects of the fisheries on the stocks, and assist salmon processors by providing a second opinion on matters of salmon fisheries management. With the high levels of production since the 1980 s, our primary objectives have been to determine how to maintain the high production (what has caused year-to-year variation) and how to harvest and process salmon most efficiently (e.g., accurate forecasts and fishing evenly distributed throughout the run).

We presently have salmon research projects in Bristol Bay, the Alaska Peninsula, and Chignik that are funded in part or entirely by the industry. In addition, we have a federally funded high seas salmon project that was focused on the oceanic distribution of salmon and the vulnerability of North American stocks to foreign fisheries, but is now focusing on ocean carrying capacity for salmon. In recent years, we have also worked in Kodiak, Southeast Alaska, and on the Yukon stocks. All of these projects have been carried out in cooperation with the Alaska Department of Fish and Game (ADFG) or the National Marine Fisheries Service (high seas), and we have also had cooperative research projects with salmon biologists from Japan and Russia. In 1996, Dr. Ole Berg (Norway) and Dr. Victor Bugaev (Russia) joined us in our field research.

This report is focused on our 1996 Bristol Bay research emphasizing salmon forecasting and research relevant to escapement policies for maximizing production. Our Chignik and Alaska Peninsula annual reports will be submitted in February.

## Forecasting

## Preseason Forecasts

Forecasts of the 1997 Bristol Bay sockeye salmon (O. nerka) runs and catches were provided to participating pro-
cessors at our October 1996 meeting (Rogers 1996). They are presented in Table 1 with the ADFG forecasts and the past forecasts and runs beginning in 1987. The two river system forecasts (FRI and ADFG) are based on the same data sources, but different analytical methods have often been used. Both 1996 forecasts were for a large run and catch, and the actual run ( 37 million) and catch ( 30 million) were smaller than forecast but within $20 \%$ of the forecasts. The outlook for 1997 is for the smallest run and catch since 1988. Egegik is expected to produce nearly $40 \%$ of the Bristol Bay run in 1997.
The next large run ( $>20$ million) to the Kvichak is likely to come in 1999. Fry from the 1994 escapement of 8 million had relatively poor growth and are likely to spend 2 years in the lake and return as adults mostly in 1999 (5 years after their parents); however, fry from the 1995 escapement of 10 million had relatively good growth and the majority are likely to spend only 1 year in the lake and thus return as adults also in 1999 (4 years after their parents). This will be confirmed if there is a very large smolt migration from the Kvichak in 1997 containing both age 1 and age 2 smolt.

## Port Moller Forecast

The Port Moller inseason test fishery was conducted by ADFG during June and early July from 1968 through 1985 with a change in gear in 1985. There was no test fishery in 1986 and, beginning in 1987, FRI has conducted the test fishery each year. The test fishery now employs a 200-f gillnet that is 60 meshes deep and has 5 -in stretched mesh. The web is multistrand monofilament (center core). Since 1994, we have used the fishing vessel Cape Cross. Fur stations have been fished along a transect 33 to 63 nm out from Port Moller ( 13 to 43 nm from point to point coastline); however, in 1995 we also made some drifts at stations 0 and 10 ( 3 and 53 nm from the coastline) and in 1996 we made 3 drifts at station 0 . Catch, mean length, and water temperature data were sent daily by radio to Port Moller and then faxed into Bristol Bay. Scales and length data were sent periodically to ADFG (B. Cross, King Salmon), where the scales were aged and the age compo-
sitions and average lengths by age were reported.
Since 1987, the forecasts have been very accurate. The runs have differed from the forecasts made on June 25 and 30 by an average of $20 \%$, and we have been within an average of $12 \%$ on forecasts made about July 3 (Table 2). We have not done as well in forecasting the catch because river system forecasts and thus catches cannot be made until about July 3, when we have the first indication of where the salmon are going. In 1996, the Bristol Bay run was earlier than average although not as early as the 1993 run (Fig. 1). The distribution of the sockeye as they passed Port Moller was somewhat unusual in 1996 as the sockeye were located closer to shore than in past years and were especially scarce at the outermost station (station 8; Fig. 2). The test-fish catches projected that the 1996 run would be early in timing but still overforecast the run magnitude because the run was distributed closer inshore and the sockeye were larger than average and thus more vulnerable to the 5 in mesh.

ADFG (B. Cross, Anchorage) provided preliminary length and weight statistics for 1996, and statistics from prior years were available (e.g., Yuen et al. 1981, Stratton and Crawford 1994) from which we could calculate mean lengths in the runs (Table 3). Both the 2-ocean and 3ocean sockeye salmon in the 1996 run were about average in length; however the average length of all sockeye in the run was well above average because 3-ocean fish constituted $76 \%$ of the 1996 run. Because there were higher percentages of 3-ocean fish in the eastside districts, the average sockeye caught there was about $20 \%$ heavier than the sockeye caught in the Nushagak district (Tables 4 and 5).

In 1996, the Port Moller test fishery provided an early indication to ADFG management that a large run was on the way, and the age composition suggested a large Egegik run. Although there was some overescapement in the Wood and Igushik rivers, the escapements in 1996 were closer to the goals than in any of the past 7 years (Table 6). Considering the situation in the Naknek/Kvichak district (a large Naknek run and small Kvichak run), management of the fishery was very good with a $84 \%$ harvest rate on the Naknek run and only $58 \%$ on the weaker Kvichak run. Good catches were made in all districts before large numbers of fish were counted past the towers.

## Lake Research

During the summer of 1996 , we continued our longterm studies of spawner distribution, growth and abundance of fry, and the physical and biological environment for the sockeye salmon of the Wood River (Nushagak) and

Kvichak lake systems. However, funding was reduced by about $30 \%$ in 1996 and this required that we reduced our field work in the Wood River Lakes by 1 week and in the Kvichak by 2 weeks. Most of our annual observations in the Wood River Lakes extend over more than 40 years and constitute the longest continuous biological and environmental record on any salmon stock in Alaska. In 1996, we also conducted special studies of bear predation on spawning sockeye salmon and the effects of spawning salmon on stream biota, especially insects. In addition, we provided a crew to ADFG for their Nuyakuk escapement enumeration and paid for the flying time necessary for ADFG to conduct aerial surveys of the Wood River spawning grounds.

## Kvichak System

Our 1996 field season in the Kvichak system (Lakes Iliamna and Clark) consisted of the following: estimating the sockeye salmon escapement into the Newhalen River in late June and July, townetting for juvenile sockeye salmon and threespine stickleback (Gasterosteus aculeatus) in upper Lake Iliamna in August, and conducting spawning ground surveys in late August to collect otoliths for sockeye age determination. We did not tow in Lake Clark nor survey several spawning grounds that are usually sampled in September. In addition, we greatly curtailed our studies on the ecological relationship between sockeye salmon and sculpins, genetic differentiation of sockeye salmon spawning populations and spawning behavior of sockeye salmon.
Two MS theses were completed in 1996 on field work carried out in 1995. Studies of the potential competition between juvenile sockeye salmon and least cisco (Coregonus sardinella) in Lake Clark (Schlenger 1996) and the spawning behavior of island beach spawners in Lake Iliamna (Leonetti 1996) were completed. In addition, a paper on the effects of varying sex ratios on spawning behavior of Lake Iliamna beach spawners was published (Quinn et al. 1996)
Newhalen River Escapement.-The annual escapements of sockeye salmon to the Kvichak lake system are estimated by ADFG from expanded $10-$ min counts on each bank of the river near Igiugig at the outlet of Lake Iliamna. Since 1979, we have estimated escapements up the Newhalen River by expanding 20-min counts, for each of 10 daylight hours, on the northwest bank of the river at the town of Newhalen. We assume that fish use both sides of the river equally and that day and night migration rates do not differ. The daily counts at Newhalen are compared
with those from ADFG at Igiugig to estimate a travel time. We calculate the daily proportions of the run at Igiugig that went up the Newhalen by lagging the Newhalen counts back the appropriate number of days.

The cumulative daily escapements for the two rivers, timed to the Kvichak River, are given for 1991-96 (Table 7). In mid-July, milling fish often swim upriver along the banks of the Newhalen and are counted only to drift uncounted back down in the middle of the river, and return upstream to be counted again. This behavior inflates the counts for the escapement; therefore, we have used the average proportion of the Newhalen count to Kvichak count for day 5 to day 16 (day 1 equals the first day of about 100,000 in the Kvichak) and the season's total Kvichak escapement to estimate the Newhalen/Lake Clark escapement.

In 1996, we estimated that only 36,000 of the Kvichak escapement of 1.45 million (about $2 \%$ ) migrated to the Newhalen/Lake Clark system (Table 8). The aerial surveys conducted by ADFG in 1996 (Regnart 1996) provided an estimate of the Newhalen River spawners $(4,000)$ and, thus, by subtraction, an estimate of the Lake Clark escapement of only 32,000 , the smallest number on record.

Spawning Ground Surveys.-Each year since 1956, we have collected scales or otoliths from spawned-out sockeye salmon from nine major spawning grounds in the Kvichak River system. In 1996, we only sampled four of these in Lake Iliamna-three beaches and one river (Table 9). Overall, the age pattern was similar to the composition of the entire lake system (Kvichak escapement). However, age 1.3 fish were scarce in the island beach populations and age 1.2 fish were somewhat scarce in the Gibralter River samples.

We had conducted annual aerial surveys of the Kvichak spawning grounds from 1956 until 1988, after which ADFG took over the surveys. The results of the 1996 survey were reported by Regnart (1996). These are summarized for 29 spawning grounds (Table 10). Aerial counts accounted for $17.8 \%$ of the relatively small (tower count) escapement into the Kvichak system. This percentage is higher than average for recent years but comparable to percentages counted in the 1960s and 1970s. Most of the 1.45 million escapement in 1996 returned to the rivers in Lake Iliamna with very low numbers of spawners on the lake beaches and in Lake Clark.

Sockeye Fry Abundance and Size.-We have sampled the sockeye fry (age 0) in the Kvichak system in August of each year since 1962 (1961 brood year) by townetting set stations in Lakes Iliamna and Clark at night. In 1996, we sampled 11 sites in the eastern portion of Lake Iliamna. The geometric means of the catches per 20-min trawl pro-
vide a measure of the relative density. The mean lengths of fry adjusted to their predicted size on September 1 (based on daily growth estimates) provide a measure of the growing conditions for that year and can be used to estimate the proportion of fry that will migrate to the ocean at age 1 or 2.
The sockeye salmon fry of Lake Clark are usually smaller than those in Lake Iliamna because of the lower productivity of the lake, which results from both colder water temperatures and increased turbidity. In 1996, sockeye fry from Lake Iliamna averaged 62 mm and were slightly larger than the long-term average of 57 mm (Table 11). On the basis of an average size of 62 mm for Iliamna fry on September 1, we estimate that about $70 \%$ of fry resulting from the 1995 brood year will smoltify and migrate to sea in spring 1997, and about $60 \%$ of the adult production from the 1995 escapement of 10 million will return at age 1.2 in 1999.
Predation of Sockeye Eggs by Coastrange and Slimy Sculpins.-Since 1992, we have monitored the predatory intensity of sculpin species (Cottus cognatus and $C$. aleuticus) on sockeye salmon eggs during the sockeye spawning season. In 1996, we limited our work to surveys to the relative abundance and size of sculpins on some island beaches. If sculpin predation on sockeye eggs is a major factor in the cyclic nature of island beach spawners as we have hypothesized, then in years of low sockeye abundance, like 1996, sculpins should have a greater impact on the sockeye than in years of high spawner abundance. However, this was not the case in the three beaches surveyed in 1996. While sockeye abundance was the lowest observed in 5 years, the relative numbers of sculpins was even lower. Further, the large size classes of sculpins that can eat the most eggs and which have dominated in our previous surveys, were largely absent in 1996. Sculpins appear to have significant effects on sockeye spawning (duration and coordination) but, so far, not on the cycle of sockeye production.

Pedro Bay Spawning and Predation Studies.-In addition to river and beach spawning populations, Lake Iliamna also has a number of sockeye salmon populations that spawn in ponds fed by cold spring water. Pond spawning gravel has a very high proportion of fines in the spawning gravel, as would be expected from the low, controlled underground spring water flows. For the past 3 years, we have measured various aspects of the spawning ecology and behavior of sockeye salmon in the Pedro Bay ponds in an attempt to determine whether they have specifically adapted to this unique spawning (and possibly rearing) environment.

In 1996 we continued our observations of patterns of sockeye salmon habitat use and predation by brown bears.

Previous observations had revealed a low predation rate in 1994 ( $10 \%$ of males and $4 \%$ of females killed) and a high rate in 1995 ( $97 \%$ of males and $70 \%$ of females killed). However, salmon inevitably die after spawning, so predation by bears is not important for salmon unless it takes place before the females spawn. In 1994 and 1995, the great majority of females killed by bears had already spawned; however, in 1996 a relatively small population of spawning salmon and an exceptional abundance of bears resulted in $100 \%$ predation during our period of observation. Virtually no male salmon were seen and the ponds that had supported thousands of spawners in previous years had only a few redds. In all but the largest pond, most salmon were killed within a day of arrival. This heavy predation precluded sampling for age and size but will present a rare opportunity to examine the population-level response in subsequent years to the low number of spawners in 1996.

Sockeye Spawning Behavior Studies.-In 1996, we extended our studies on the role of color in spawning behavior. We are interested in the role of carotenoid-based red skin pigment in mate selection. Carotenoids are plant synthesized compounds that are bio-accumulated throughout the food chain. Sockeye salmon get their carotenoids largely from krill in the ocean. Carotenoids account for the orange-red color of sockeye salmon flesh. With the help of visiting scientists from the Universities of Victoria and British Columbia, and the US Fish and Wildlife Service, we measured the spectral characteristics of island beach waters and spawning sockeye salmon. We then tested what aspects of color (wavelength and brightness) male sockeye respond to in controlled experiments conducted on the spawning beaches. Males responded mainly to wavelength and only secondarily to brightness. Therefore, males can use color (wavelength) to select mates even during dusk and dawn when brightness is much reduced. Higher wavelengths (red) are relatively more abundant during these periods (accounting for red sunsets and sunrises); thus, the color red may provide an enhanced effect throughout most of a $24-\mathrm{h}$ period.

## Wood River System

The Bristol Bay research program of FRI began with spawning ground surveys in the Wood River Lakes in 1946 to determine where, when, and how many sockeye spawned there. During the early 1950s, methods were established to enumerate and sample the commercial catches, escapements (towers), and the smolts produced. By the late 1950s, we had established several important measurements, which we have maintained to the present in or-
der to characterize each year's environment for spawning adults and rearing juveniles.
In 1996, our field season was shortened by 1 week, which resulted in the loss of townetting in the north arm of Lake Nerka, zooplankton and temperature sampling in the upper lakes, and the collection of otoliths for age determination from 4 of the 21 spawning grounds that we normally survey. During 1996, an MS thesis was completed on the impact of spawning sockeye salmon on resident fish-rainbow trout (O. gairdneri), Arctic char (Salvelinus alpinus), and Arctic grayling (Thymallus arcticus). Rainbow trout and char depended heavily on salmon eggs while grayling consumed very few (Eastman 1996). Another MS thesis was completed on a comparison of zooplankton populations in lakes with and without sockeye salmon. Zooplankton densities generally declined towards the end of the summer in those lakes with juvenile sockeye (presumably from predation), whereas there was a general latesummer increase in zooplankton in the lakes without salmon (Reischauer 1996).
Effects of Spawning on Invertebrates.-A new study was conducted in 1996 that focused on the impact of salmon spawning (redd excavation) on the substrate and aquatic community of two small streams. Observations in Bear and Whitefish creeks on Lake Aleknagik included assessment of changes in the physical habitat (gravel size), periphyton density, invertebrate density, and the foraging of resident fishes. Preliminary results indicate that a substantial increase in invertebrate drift accompanies the entry of spawning sockeye into the streams. This may result in an increase in available food for resident fishes.

Environmental Observations.-Spring 1996 was early and ice breakup in Lake Aleknagik (recorded since 1949) was 7 d earlier than average (Table 12 and Fig. 3). Early summer water temperatures were above average because solar radiation (sunlight) was above average during early June; however, for the entire summer, solar radiation was again lower than during the 1960 s to early 80 s. Water temperatures actually declined from early August to early September. Lake levels were well below normal in early June as a result of a small snow pack and lake level continued to be well below average for the remainder of the summer. Standing crop of phytoplankton (chlorophyll) was below average throughout the summer (fifth lowest since 1963), whereas zooplankton volumes were a little above average until September (Fig. 4). Zooplankters are the main source of food for juvenile sockeye salmon after they move offshore in late July. Insects (mainly pupal and adult midges) are the main source of food in the spring when the fry are inshore. There was an early peak in midge emergence in

1996 (mid-July) corresponding with the early ice breakup. In past years, midge emergence has usually peaked in either late July or early August (Table 13). Water temperature at the nearshore insect traps was warmer than average in 1996, but no records were set.

Fry Abundance and Growth.-In 1996, the sockeye salmon fry in Lake Aleknagik were 3\% longer than average in June, but their growth during July and August was below average, and on September 1 they were $2 \%$ shorter than average (Table 14). Fry abundance, as measured by beach seine sampling in June and July and townet sampling around September 1 , was only $34 \%$ below the longterm average. The number of parent spawners $(482,000)$ in Lake Aleknagik in 1995 was above average for the lake. The relatively small size on September 1 indicates that the fry and sticklebacks had cropped down their main food supply, especially the larger forms of the zooplankton such as calanoid copepods, Holopedium and Daphnia (Table 12). The adult returns to Lake Aleknagik have generally been large since 1978 even though fry abundances have often been low. This suggests that recent large runs have been caused mainly by improved ocean survival.

The mean lengths of sockeye salmon fry in Lake Nerka indicated that, in 1996, growth was above average; however, we were unable to tow in the north arm of the lake. Townet catches were above average in the central region of the lake (Table 15). Juvenile sockeye salmon in the Wood River Lakes system exhibit density-dependent growth, and we are analyzing our long-term data set for Lake Aleknagik to determine the relative effects of physical and biological factors in the lake on the growth of the sockeye salmon fry. In addition, we are examining year-to-year variation in zooplankton population composition along with annual variation in sockeye salmon fry and threespine stickleback abundance to determine the extent to which the fish alter their food resources. We hope the information from these studies will help explain the observed variability in the freshwater phase of the sockeye salmon.

Arctic Char Predation.-Each spring when sockeye salmon smolt are migrating seaward from the Wood River lake system, Arctic char concentrate in and around the interconnecting rivers to feed on the smolt. We conducted several studies of this predation during the 1950s to 1970s and since then we have sampled the char in Little Togiak River on an opportunistic basis. In 1996, we caught, measured and examined stomach contents of 40 char during June 16-20 (Table 16). The char were about average in length and a typical percentage (42\%) contained sockeye salmon smolt in their stomachs.

Spawning Ground Surveys.-Surveys of sockeye salmon spawning grounds have been conducted annually in the Wood River Lakes system since 1946; however, it was not until the early 1950s that all of the major spawning grounds were included. We collect otoliths from the major spawning grounds for age determination and make ground counts of the number of spawners in the small streams. ADFG estimates the numbers of spawners on the lake beaches and in the interconnecting rivers by aerial surveys; thus, the total escapement to the lake system can be apportioned to the individual lakes or type of spawning ground (creek, river, and beach). The distribution of spawners among the lakes is used in forecasting the Wood River runs. Even escapement distributions tend to produce larger returns than uneven distributions.
Aerial surveys were conducted by ADFG in 1996. The ground survey counts in 1996 for the major creek spawning grounds are given in Table 17. The creeks draining into Lake Aleknagik again contained relatively high counts of spawners. Hansen Creek contained a large number of spawners for the seventh consecutive year. Age compositions on the spawning grounds in 1996 varied in a typical manner with 3 -ocean fish prominent in the rivers and some creeks while 2-ocean fish were preponderant on the beaches and creeks in Lake Nerka (Table 18).
Bear Predation.-We completed the seventh year of our bear/spawning sockeye salmon interaction study in Hansen Creek, a small tributary of Lake Aleknagik where predation by bears is high relative to larger creeks. During 18 July to 24 August, a large number of spawners were again observed in Hansen Creek (Table 19). Daily count and removal of sockeye salmon killed by bears indicated that $2,800(30 \%)$ of 9,736 spawners were killed by bears in 1996 (Table 20). These estimates excluded dead fish from previous daily surveys that might have been attacked by bears (decisions to exclude fish were based on gill and body coloration, body firmness, and body deterioration). The number of sockeye killed by bears in 1996 was about average for the 7 -year period. Our experiences during stream surveys in 1995 suggested that the bear population had increased in the Wood River Lakes system; however, bear sightings were greatly reduced in 1996. We plan to continue the daily surveys in Hansen Creek until we obtain counts for a year when the number of spawners is near the median $(2,500)$ and for a year when there is a small number of spawners $(<1,000)$.
The daily counts on Hansen Creek are also providing us with estimates of the percentages of the total number of spawners that are counted on a single "peak survey" date
and, thus, a means of adjusting our annual survey counts to equal the true number of spawners. Hansen Creek has been surveyed most often on August 6 in past years; but in $20 \%$ of the years, the survey was done on August 1 or earlier. The Hansen Creek sockeye salmon are about the earliest spawners in the lake system and the fish usually first enter the creek about July 22-25. On the basis of daily counts in 1990-96, if the surveys had been conducted on the single date of August 6 , the peak survey counts would have been $69 \%$ to $89 \%$ of the totals; if the single surveys were done on August 1, the counts would have been $38 \%$ to $78 \%$ of the actual number of spawners (Table 20).

1. Beach seine catches at 10 stations for four dates during 6/22-7/14.
2. Tow net catches for 5 -min hauls, two at each of six stations during Sept. 1-5.
3. Lengths measured to nearest mm on preserved fish, means adjusted to live measurement.
4. Threespine stickleback catches are for all ages ( $0-4$ ), but mean lengths for age 1 only.

Table 15. Average townet catches and mean lengths of sockeye salmon fry (by lake area), number of parent spawners, and average catches and mean lengths (age 1) of threespine stickleback for Lake Nerka.

| Year | Sockeye salmon fry |  |  |  |  |  | Sockeye salmon spawners in year-1 (1000s) |  |  | Threespine stickleback |  |

| Totals |  |  | 5567 | 2687 |  | 909 | 113 |  |  |  |  |

Dead fish removed on each survey.
Dead counts from the side pond only through $8 / 18$. Both ponds counted on $8 / 24$.

34 / Rogers et al.

Table 20. Summary of Hansen Creek spawning surveys, 1990-96

[^0]:    *Strike in 1991 delayed the start of fishing except at Ugashik.
    **Upper range of escapement goals for Egegik and Ugashik were increased to 1.4 and 1.2 million for 1995 .

[^1]:    * Partial count; entire stream not surveyed.
