**Abstract**

Vaccination Trends in Bangladesh and Mozambique: Small area estimation of routine childhood vaccinations 1991-2013

Rebecca Engell

Chair of the Supervisory Committee:

Associate Professor Stephen S Lim

Department of Global Health

**Background** In many countries, vaccine-preventable diseases remain major causes of child mortality. Childhood vaccination is one of the most cost-effective and efficient ways of protecting the health of children across the globe. As countries strive towards universal vaccination coverage, the value of timely, robust and high-quality estimates of vaccination coverage at local-levels becomes increasingly valuable. We produced sub-national estimates of vaccination coverage for BCG, measles and the third dose of oral poliomyelitis (OPV3), and diphtheria-tetanus-pertussis (DTP3) in Bangladesh and Mozambique.

**Methods** We estimated childhood vaccination coverage by analyzing unit record data from household surveys. Data was mapped to the lowest administrative unit possible either from GPS coordinates or a survey variable. We used a small area geospatial model with intrinsic conditional autoregressive (ICAR) random effects to model spatial variation in districts and provinces in Mozambique and districts and upazilas in Bangladesh. A spline function was used to model temporal trends, and spatial-temporal interaction terms were specified to capture the variation in local-level patterns of vaccination coverage. Time series were generated for the years 1991-2013 for the 64 districts in Bangladesh and for the period 1997-2008 for 426 upazilas in Bangladesh. Estimates for Mozambique's 11 provinces were produced for the period 1994-2013 and for 148 districts in 2011.

**Findings** Vaccination coverage in Bangladesh and Mozambique increased across antigens in the last twenty five years. Nationally, coverage of DTP3 rose from 67.5% (44.3-81.4) in Bangladesh in 1995 to 98.9% (86.1-99.9) in 2013. Mozambique achieved smaller relative growth and at lower absolute levels: DTP3 coverage was 61% (58-64.6) in 1994, increasing to 76.9% (73-80.6) in 2013. The lower administrative level estimates highlight intra-district and intra-province variability that suggest vaccination coverage does not follow administrative boundaries. The disparities between highest and lowest performing upazilas in Bangladesh decreased over time – the mean standard deviation for DTP3 coverage was 15.5% (14.2-17.1) in 1997, shrinking to 6.8% (6.2-7.7) in 2008 as more upazilas achieved higher levels of vaccination coverage. Variation among provinces in Mozambique also decreased - the standard deviation for measles vaccination between provinces was 17.5% (14.8-19.2) in 1995 and remained at 11.6% (9.1-13.7) in 2013. Among districts in Mozambique, full vaccination had the largest standard deviation at 16.0% (14.1-19.5%) in 2009. BCG vaccination coverage was the most equitable with a standard deviation of 10.5% (9.9-11.1).

**Interpretation** The sub-national analysis in both countries illustrates a more nuanced story of success and missed opportunities, as well as distinctive geographic patterns to vaccination which are masked at higher administrative levels of analysis. These results should be taken as a call to action for more local-level data collection and data analysis efforts, and should bring attention to sub-national efforts to improve service delivery and access to childhood vaccinations in Bangladesh and Mozambique.

## Introduction

In many countries, vaccine-preventable diseases remain major causes of child mortality.<sup>1</sup> Measles, tetanus, diphtheria, pertussis, tuberculosis, influenza, pneumococcal and Hib pneumonia, and rotavirus remain in the top twenty causes of child mortality in 173 countries across the globe. Childhood vaccination is estimated to prevent approximately 3.2 million deaths annually,<sup>2-4</sup> and is one of the most cost-effective and efficient ways of protecting the health of children across the globe. The last 40 years have seen tremendous resources invested globally to create and scale up vaccination programs.<sup>5,6</sup> Resources have also been invested in health information systems and household surveys to track progress towards equitable and increased vaccination rates. Timely, high-quality measurement of vaccination coverage is critical to understanding if and where improvements have been made, and identifying underserved areas for targeted interventions. Many low and middle-income countries have routine national household surveys and health information systems which can be used to estimate vaccination coverage at the national level. However, there is a dearth of robust sub-national level data, particularly at second and third administrative units. Producing precise sub-national vaccination coverage is important as countries continue to improve delivery mechanisms and strive towards universal childhood vaccination. Using Bangladesh and Mozambique as case studies, we attempt to illustrate the value of small area estimation by producing time series for vaccination coverage in each country at sub-national levels.

Bangladesh is located in Southern Asia, bordered by the Bay of Bengal, between Myanmar and India. Situated within the delta between the Ganges and Brahmaputra rivers, about 20% of the country is subject to annual flooding, isolating communities from economic and social opportunities, as well as education and health services.<sup>7</sup> Bangladesh is the eighth most populous country in the world with approximately 153 million people and an average annual growth rate of 1.34% nationally.<sup>8</sup> The country has recently been applauded as an exceptional health performer, achieving substantial reductions in mortality and morbidity in the forty years since independence despite staggering poverty, severe and recurrent natural disasters, and a low gross domestic product.<sup>9</sup> Investments in primary health care, including vaccinations, are thought to be a large factor in the country's health gains.<sup>9,10</sup>

Bangladesh officially initiated its EPI program in 1974, with programmatic momentum occurring after the country's 1985 UN commitment to reach universal vaccination coverage by 1990. Government investments and strong support and technical training from multiple partners helped to expand vaccination delivery across the country and improve demand generation.<sup>11</sup> Subsequently, vaccination coverage among children 12-23 months increased from 2% in 1986, to 59% in 1993-4, to nearly 82% in 2007.<sup>12-14</sup> However, despite this tremendous growth, gaps in vaccination coverage remain. National coverage for BCG vaccination is almost 20 percentage points higher than coverage rates for all childhood vaccinations (98.6% vs 79.4%).<sup>15</sup> District differences and differences by socio-demographic indicators such as maternal education and rural/urban location persist, emphasizing the challenge of reaching all segments of the population.<sup>16</sup>

Mozambique, located in south-eastern Africa, has had a very different picture of health and health systems development over the last forty years. A country of approximately 22.4 million people, it has been hit hard by a brutal civil war from 1977-1992 and a substantial HIV epidemic. The civil war, coming after the war for independence, impeded development of government infrastructure, including health services. Health and education services have also lost significant fractions of their work force due to HIV/AIDS, leaving gaps in basic service provision.<sup>17</sup> Mozambique's EPI program, which began in 1979, is delivered predominantly through vaccination days at health facilities throughout the country. Unfortunately, only 50% of the population is served by the existing health network.<sup>18</sup> As a result, vaccination coverage in Mozambique remains low – only 59% of children 12-23 months old in 2011 had received three doses of DTP.<sup>19</sup> Large variation exists across the country's eleven provinces and by

antigen. For example, the 2011 DHS survey estimated 81.5% of children nationally had received measles vaccination, with a range of 71.5% in Zambézia to 98.1% in Maputo Province.<sup>19</sup>

Both countries have placed a large emphasis on improving sub-national trends in child health. In 2004, the Government of Bangladesh and UNICEF launched a “Reach Every District” (RED) campaign to emphasize local-level planning to improve vaccination coverage in the lowest performing districts. In 2007 this approach was further intensified when WHO and UNICEF started programs in a total of 38 districts to increase DTP3 coverage in response to high dropout rates – 23 LAUNCH districts and 15 low-performing districts. Mozambique also launched the RED strategy, beginning with a phased in rollout on a district-by-district basis in 2008. National Mother and Child Health weeks have been conducted twice a year since 2008 as an additional strategy to improve vaccination coverage among children who are not accessing fixed EPI sites.

The district level focus on health interventions in Bangladesh and Mozambique must be accompanied by high-quality, robust data collection, and analysis at or below the district level to successfully monitor program implementation and track progress. Despite the availability of health information from surveys and administrative data, concerns about quality have undermined their use in Bangladesh and Mozambique.<sup>22,23</sup> A 2009 assessment on the Bangladeshi Health Information System (HIS) stated that most of the data it collects is of poor quality and that data management and coordination between collection agencies is poor or non-existent.<sup>24</sup> The Coverage Evaluation Survey, although district-representative, has no published validation procedures or uncertainty estimates. It is also not powered to detect differences by socio-demographic group or by gender at the district level.

There is a need for sub-province analysis in Mozambique, and in Bangladesh, sub-district analysis, if these countries are to be efficient and effective in improving sub-national child health. With a more local level view on health, officials and policymakers can better identify areas of stagnating or falling vaccination coverage. High performing areas can also be identified as case studies for programmatic improvements. Patterns of vaccination coverage may not follow administrative boundaries; restricting analysis to the higher administrative levels may limit understanding of the full degree in variation in vaccination coverage.

Small area measurement methods offer the opportunity to use existing data for more precise and accurate local-level information than can be achieved through direct estimates from surveys or administrative records. Bangladesh and Mozambique currently use a combination of standardized sample surveys and administrative data to report vaccination coverage at the national and second administrative levels. In Bangladesh, there is additionally the Coverage Evaluation Survey (CES) which is conducted annually to estimate district-representative vaccination coverage.<sup>25</sup>

Small area models are statistical models which address the issues raised by small sample sizes by explicitly accounting for the large sampling variance and exploiting spatial and temporal relatedness to increase predictive power. Employing such models in Bangladesh and Mozambique allows one to use existing data sources to achieve finer-level administrative estimates of vaccination coverage. Systematically compiling sources for these models grants perspective on the full landscape of health data for a particular intervention, and usually expands the time period over which one can estimate. Pooling over sources not only increasing sample size but also addresses concerns that a particular source may be unreliable. The compilation can illustrate the bias in any one source and either smooth across these differences or outlier specific sources.

As Bangladesh and Mozambique continue to improve their responsiveness to health information and make evidence-based policy decisions, using smaller and smaller administrative units as the base of analysis becomes increasingly valuable. In this study we utilize national data sources to estimate

childhood vaccination coverage at second and third administrative levels in both countries, in hopes of better identifying areas of success and missed opportunities to improve child health.

## Methods

We estimate childhood vaccination coverage at the province and district levels in Mozambique and for districts and upazilas in Bangladesh using a single-stage small area geospatial model. We systematically collate and estimate coverage based on all available household surveys from unit record data. We produce estimates using a single-stage geospatial small-area model for each of the 11 provinces in Mozambique for the time period 1994-2013 and for all 148 districts in 2011. In Bangladesh, our estimates include a district time series for the period 1991-2013<sup>1</sup> and upazila estimates for the time period 1997-2013. To the best of our knowledge, this is the first time series at this administrative level.

As in most WHO member states, Bangladesh and Mozambique offer immunization against the six basic antigens. The EPI schedule includes the administration of Bacillus Calmette-Guerin (BCG) and oral poliomyelitis (OPV) at birth, three doses each of pentavalent, and OPV vaccines at 6, 10 and 14 weeks and measles vaccination at age 9 months. The pentavalent vaccine includes protection against diphtheria, tetanus, pertussis, Hepatitis B, and *Haemophilus influenzae* type B. In Bangladesh, a second dose of measles is offered at 15-18 months.

## Data

We identified all available survey data sources in Bangladesh and Mozambique with information on routine childhood vaccinations; these included the DHS and MICS, and in Bangladesh the CES. A total of fifteen household surveys in Bangladesh and four household surveys in Mozambique were identified. We additionally used the two most recent censuses in each country for population-weighting our vaccination coverage estimates. See Table 1 for a list of data sources.

### Data Processing

We produced estimates of antigen-specific coverage for each year of available survey data. In Mozambique, our units of analysis were the province and district as defined by the 2007 census for a total of 11 and 148 units, respectively.<sup>26</sup> Maputo City was defined as a province with 5 districts in this analysis. In Bangladesh we were constrained by the specificity of the shapefile and limits in our population numbers available through the census. We therefore were able to produce estimates for 426 upazilas and 64 districts as defined by the 2011 census.<sup>27</sup>

All household surveys in Bangladesh can be mapped to the district level. The 1993-1994 and 1996-1997 DHS, as well as the four years of the CES have a district variable included in the dataset. The four more recent DHS (1999-2000, 2004, 2007 and 2011-2012) included the latitude and longitude of each cluster; we used this to link clusters to districts and upazila. In Mozambique, only the DHS 2011 had GPS coordinates available for mapping to districts. This limited our analysis of vaccination coverage over time to the province level in Mozambique.

The DHS scrambles their GIS coordinates to protect respondent privacy<sup>28</sup>; our assigning of GIS coordinates to districts and upazilas is therefore an approximation. Urban clusters are displaced a distance up to two kilometers (0-2 km) and rural clusters are displaced a distance up to five kilometers (0-5 km), with a further, randomly-selected 1% (every 100th) of rural clusters displaced a distance up to 10 kilometers (0-10 km). For the most recent DHS in both countries, the scrambling was confined to the district such that we can be confident that all our district assignments for these years are accurate. For the other DHS in Bangladesh, there is a degree of uncertainty in the correct assignment. We estimated that approximately 27% of the clusters in the 1999-2000 DHS in Bangladesh lie within either two or five kilometers of a border, for urban and rural clusters, respectively, and thus have the potential to have been scrambled across the district boundary. For the 2004 and 2007 DHS surveys potential scrambling was 36% and 27%.

Our estimates in Mozambique are based on the three DHS conducted in 1997, 2003 and 2011, respectively. We did not include the 2008 MICS given inconsistencies with the DHS in direct estimates.<sup>29</sup>

The DHS and MICS surveys provided information for children born up to five years before the survey; the CES provided information for children 12-23 months of age at the time of the survey. For each survey, we defined crude coverage for each antigen as the proportion of children whose mothers or caregivers reported that the child received the immunization or the child had documentation of the immunization (irrespective of the timing) on an immunization card. For our higher level administrative estimates where more data was available, we used the responses recorded for children aged 12–23 months to estimate coverage 1 year before the survey, the responses for children aged 24–35 months to measure coverage 2 years before the survey, the responses for children aged 36–47 months to estimate coverage 3 years before the survey, and the responses for children aged 48–59 months to estimate coverage for 4 years before the survey. At the lower administrative levels, we did not have sufficient sample size to parse each survey into these five age cohorts. Instead, we indexed the data points for each survey to the average birth year of the children sampled. For the upazila analysis this meant the estimates from the 1999-2000 DHS were indexed to 1997, the 2004 DHS to 2001, the 2007 DHS to 2004 and the DHS 2011-2012 to 2010. In Mozambique the 2011 DHS was indexed to 2009. In Bangladesh, DTP vaccine status was not collected until the 1996-1997 DHS; we therefore estimated coverage only for the years 1995-2013 for DTP.

### Small area models

We employed a single stage geospatial model with intrinsic conditional autoregressive random effects to estimate vaccination coverage over time at each of the two administrative units in Bangladesh and Mozambique. To model spatial trends, we included a series of area-level random effects in the regression model following those proposed by Besag et al.<sup>30</sup> To capture temporal trends at the province level in Mozambique and in districts in Bangladesh, we modeled time using natural cubic splines: piecewise cubic functions which are constrained to have continuous first and second derivatives.<sup>31</sup> This allows for a non-linear but nevertheless smooth time trend. To capture the spatial-temporal interactions, we added area-level random effects to each spline basis. This allows for area-level variation in time trends within the framework of a spline model. Models were run separately for each of the eight childhood vaccinations, and for each of the administrative levels – upazilas and districts in Bangladesh and districts and provinces in Mozambique. This included coverage of BCG vaccination, one, two, and three doses of oral poliomyelitis, one, two and three doses of DTP, and measles vaccination. We additionally estimated coverage of fully vaccinated children, defined as children who have received BCG, 3 doses each of OPV and DTP, and measles vaccinations, irrespective of timing.

To ensure consistency between our estimates at different administrative levels, we rescaled our estimates from the higher administrative level to fit into the lower level estimates, a process termed raking. In addition to forcing consistent estimates, this procedure also improves the uncertainty around the lower level estimates, given the greater uncertainty due to data availability and small sample sizes. In order to rake, we first extracted the number of children 0-4 years old from the two most recent censuses in both countries. This included the 1997 and 2007 censuses in Mozambique and the 2001 and 2011 censuses in Bangladesh. All districts in Mozambique were covered by the census; in Bangladesh we were limited to 426 of the total 485 upazilas in the country due to difficulty accessing the complete set of census data for 2001. We therefore do not have upazila estimates for Dhaka, Comilla, Dinajpur and Thakurgaon districts. We next interpolated the number of children 0-4 years old for intercensal years assuming a pattern of geometric growth. The ideal population to use is the number of children aged 12-23 months as this is the population we are modeling; unfortunately this information is not available in the versions of the censuses currently available to us. The raking process was applied to 1,000 draws from the posterior distribution, from which the median and 2.5<sup>th</sup> and 97.5<sup>th</sup> percentiles were used for our final estimates of vaccination coverage with uncertainty.

We specified a normal likelihood for logit-transformed vaccine coverage (denoted  $p_{i,t}$ ), which describes the probability of observing the data given two underlying parameters:  $\theta_{i,t}$ , the mean in area  $i$  at time  $t$  and  $\sigma^2$  the variance:

$$\text{logit}(p_{i,t}) \mid \theta_{i,t}, \sigma^2 \sim \text{Normal}(\theta_{i,t}, \sigma^2) \quad (1)$$

In Bangladesh each area  $i$  is either a district or an upazila, and in Mozambique each area  $i$  is either a province or a district. We employed a logit transformation as this has the desirable property of restricting predictions of vaccine coverage for all models to between 0 and 1. The regression equation for  $\theta_{i,t}$  was specified as a linear combination of spatial effects, temporal effects, and spatial-temporal interactions.

Besag et al.<sup>32,33</sup> describe a class of models where dependence in space is given by a matrix where each element in the matrix gives the relationship between area  $i$  and area  $j$ . Besag<sup>33</sup> proposes assuming that the conditional distribution for area  $i$  depends only on ‘neighbors’ of  $i$ . Neighbors in our analysis were defined in terms of queen adjacency; areas with borders that share at least one point are considered neighbors.

Two random effects were included to model spatial trends. The first has an intrinsic conditional autoregressive (ICAR) prior:

$$u_i \mid u_{j,j \sim i}, \sigma^2 \sim \text{Normal}\left(\frac{1}{n_i} \sum_{j \sim i} u_j, \frac{\sigma^2}{n_i}\right) \quad (2)$$

Under this prior, the effect  $u_i$  for each area  $i$  is normally distributed around the mean of the effect in neighboring area, creating a spatially smooth process ( $j \sim i$  indicates that areas  $j$  and  $i$  are neighbors and  $n_i$  is the number of neighbors of area  $i$ ). The second random effect has an independent and identically distributed (IID) prior:

$$v_i \mid \sigma_v^2 \sim \text{Normal}(0, \sigma_v^2) \quad (3)$$

Under this prior, the effect  $v_i$  for each area  $i$  is independent of that for all other areas. In this analysis we included both the IID and ICAR random effects to allow for spatially-structured and spatially-unstructured heterogeneity in the data.

With more data available at the higher administrative levels in Bangladesh and Mozambique, we were able to employ natural cubic splines with area-level random effects on the spline basis to capture the spatial and temporal relationships in vaccination coverage. The degree of flexibility in the spline function can be regulated by increasing or decreasing the number of interior knots which are the points defining the regions over which each piecewise cubic function is fit. In order to have a sufficiently flexible time trend while not over-fitting the data, we used two equally-spaced interior knots. Natural splines impose the additional constraint that the functions be linear beyond the range of the data. The natural spline was implemented by introducing a series of  $K$  spline bases to the regression equation.

$$\theta_i = \sum_{k=1}^K B^{(k)} * S^{(k)}(t) \quad (5)$$

where  $S^{(k)}(t)$  gives the  $k^{\text{th}}$  spline basis evaluated at time  $t$ ,  $B^{(k)}$  represents the coefficient (fixed effect) for the  $k^{\text{th}}$  spline basis and  $K$  varies depending on the type of spline and number of knots. The intercept was absorbed in the spline bases rather than separately specified. To extend the spline temporal model to a spatial-temporal model, we added ICAR and IID random effects to each spline basis. This allows for area-level variation in time trends within the framework of a spline model:

$$\theta_i = \sum_{k=1}^K \left( \beta^{(k)} + u_i^{(k)} + v_i^{(k)} \right) * S^{(k)}(t) \quad (6)$$

At the upazila level in Bangladesh we did not have enough data points to justify using a spline function to model the temporal trend. We therefore modeled time linearly, adding the ICAR and IID random effects to the slopes as well as the intercept<sup>34</sup>

$$\theta_{i,t} = \left(\beta^{(1)} + u_i^{(1)} + v_i^{(1)}\right) + \left(\beta^{(2)} + u_i^{(2)} + v_i^{(2)}\right) * t \quad (4)$$

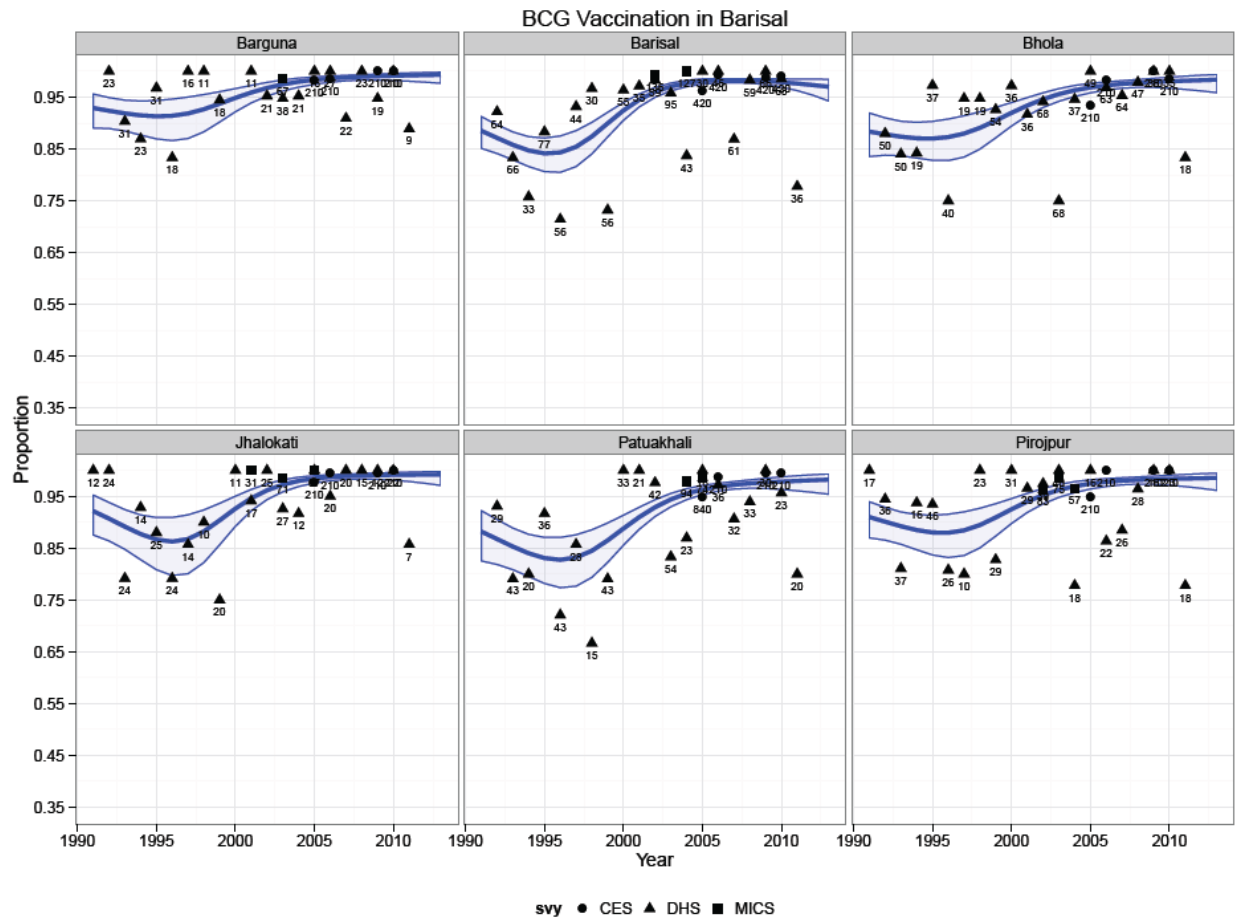

For districts in Mozambique, the model did not have a temporal component, because we had only one year of data with district identifiers. Our model therefore included only fixed and random effects to capture the spatial pattern to vaccination coverage.

All models were fit using the INLA program<sup>35</sup> in R version 2.15.2.<sup>36</sup>

## Results

We provide coverage estimates for each of the eight routine childhood vaccinations, as well as full vaccination coverage, for 426 upazilas and 64 districts in Bangladesh, and 148 districts and 11 provinces in Mozambique in the **Error! Reference source not found.** The main results presented in this paper will include coverage rates for BCG, DTP3, OPV3, measles and full vaccination.

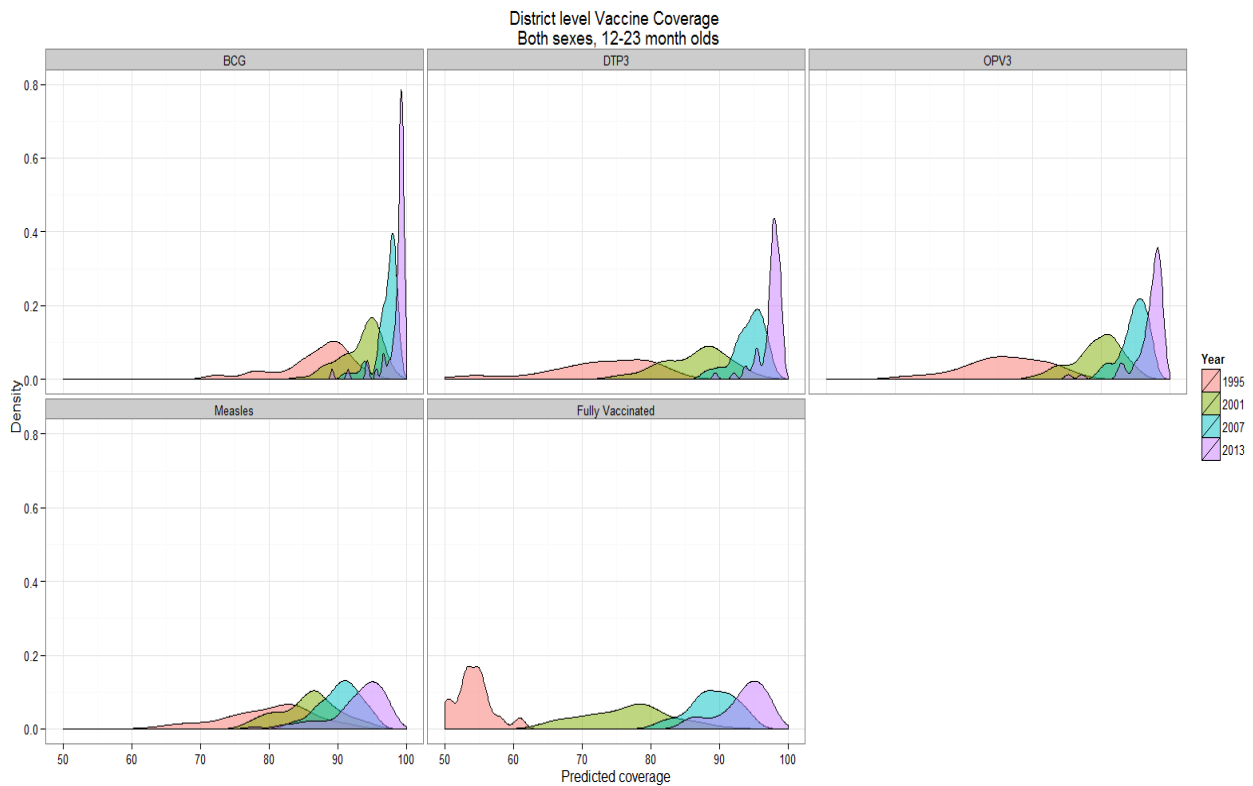

Figure 1 below is an example of the modeled vaccination results over time against the direct survey estimates, along with the sample sizes for each data point. This is shown to illustrate the value of modeling vaccination coverage across data sources and over time – the modeled results are consistent with the majority of the data and provide a smoothed trend over time. The uncertainty intervals reflect variability in the point estimates as well as the sample sizes – our estimates are less precise in the early 1990s in Bangladesh and at the lower administrative levels in both countries.

**Figure 1: District level BCG vaccination in Barisal division, Bangladesh**

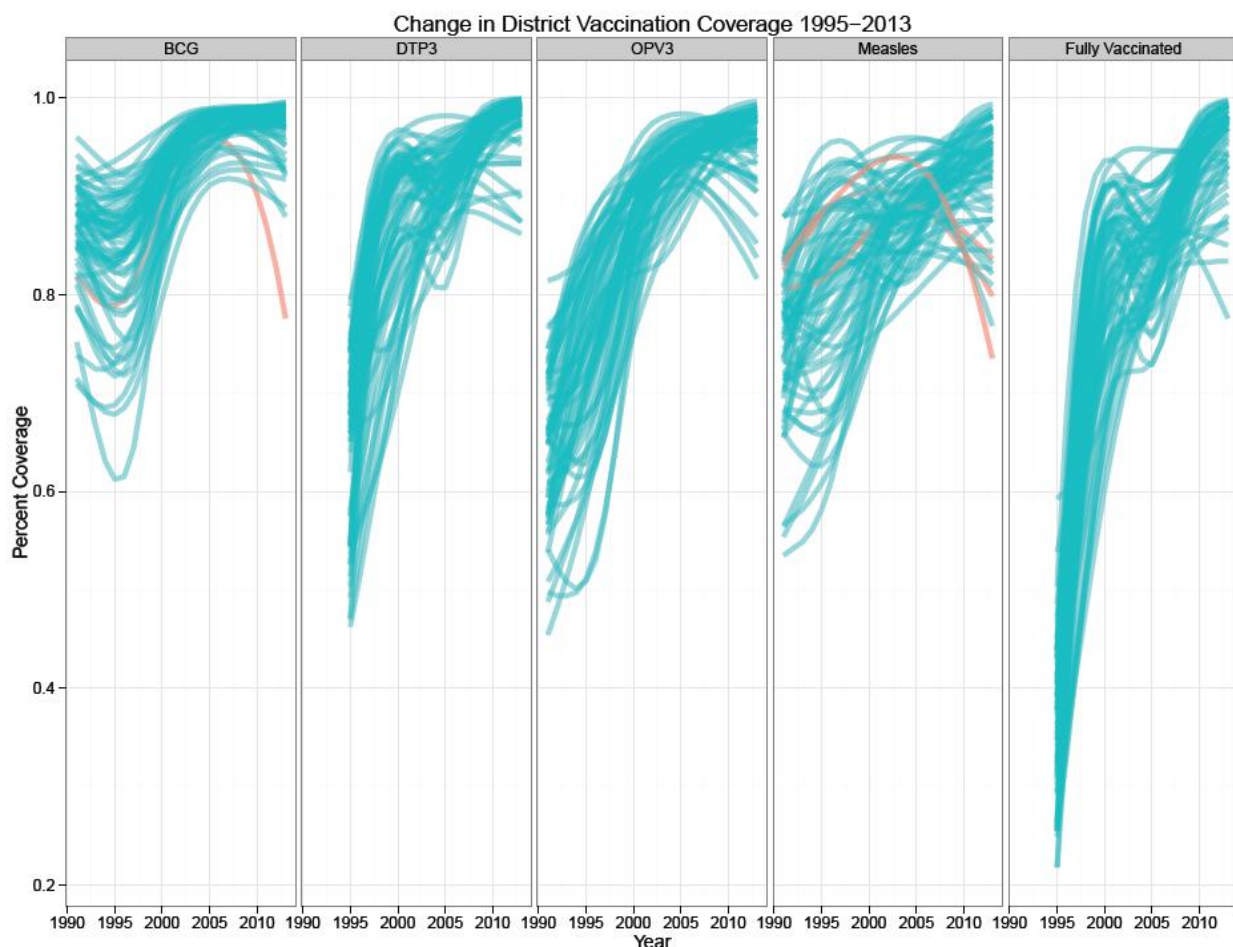

Vaccination coverage for each antigen has increased by at least 10% nationally since the 1990s in Bangladesh. The national average for BCG coverage in 2013 was 97.8% (85.5-99.7), followed by 97% (82.9-99.5) for OPV3, and 94% (75.6-99.1) for measles. These rates represent absolute increases of 10.4%, 31.9%, and 18.2% since 1991 for BCG, OPV3, and measles, respectively. Since 1995, coverage for DTP3 and full vaccination has risen 31.4% and 60% such that in 2013, coverage for these antigens was 98.9% (86.1-99.9) and 91.2% (81.2-99.7, respectively).

Estimates at lower administrative levels in Bangladesh illustrate a more nuanced picture of increasing coverage throughout the last twenty five years. As displayed in Figure 2, coverage for each antigen has increased steadily across districts in Bangladesh since the mid-1990s with the most growth in BCG vaccination. Additionally, the distribution in coverage has narrowed, suggesting more equality in vaccination coverage rates across the country. Full vaccination coverage has moved from extremely low rates in 1995 to 95% coverage in two-thirds of districts in 2013.

**Figure 2: Distribution of district level vaccination coverage, Bangladesh**

As Figure 2 illustrates, gaps in vaccination coverage have decreased across time in Bangladesh. The left tail in the distribution of coverage rates has gotten substantially shorter; the number of districts with coverage below 80% has dramatically decreased since 1995. However, progress, and the acceleration of progress, is not even across antigens, as further highlighted by the variable slopes in Figure 3 below. The rate of full vaccination among children has increased the most dramatically between 1995 and 2013 with an average relative change of 51% (range 35.2 – 66.9%). The districts that have had the largest increases for DTP3 also have the largest increases for measles and BCG, suggesting systems strengthening and improved access for services across antigens, not just one in particular. There were three districts, Khagrachhari and Rangamati in Chittagong division and Bagerhat in Khulna division, with declining measles coverage; BCG coverage in Bandarban district, Chittagong division decreased by one percent between 1995 and 2013.

**Figure 3: Absolute change in district vaccination coverage, 1995-2013, Bangladesh**

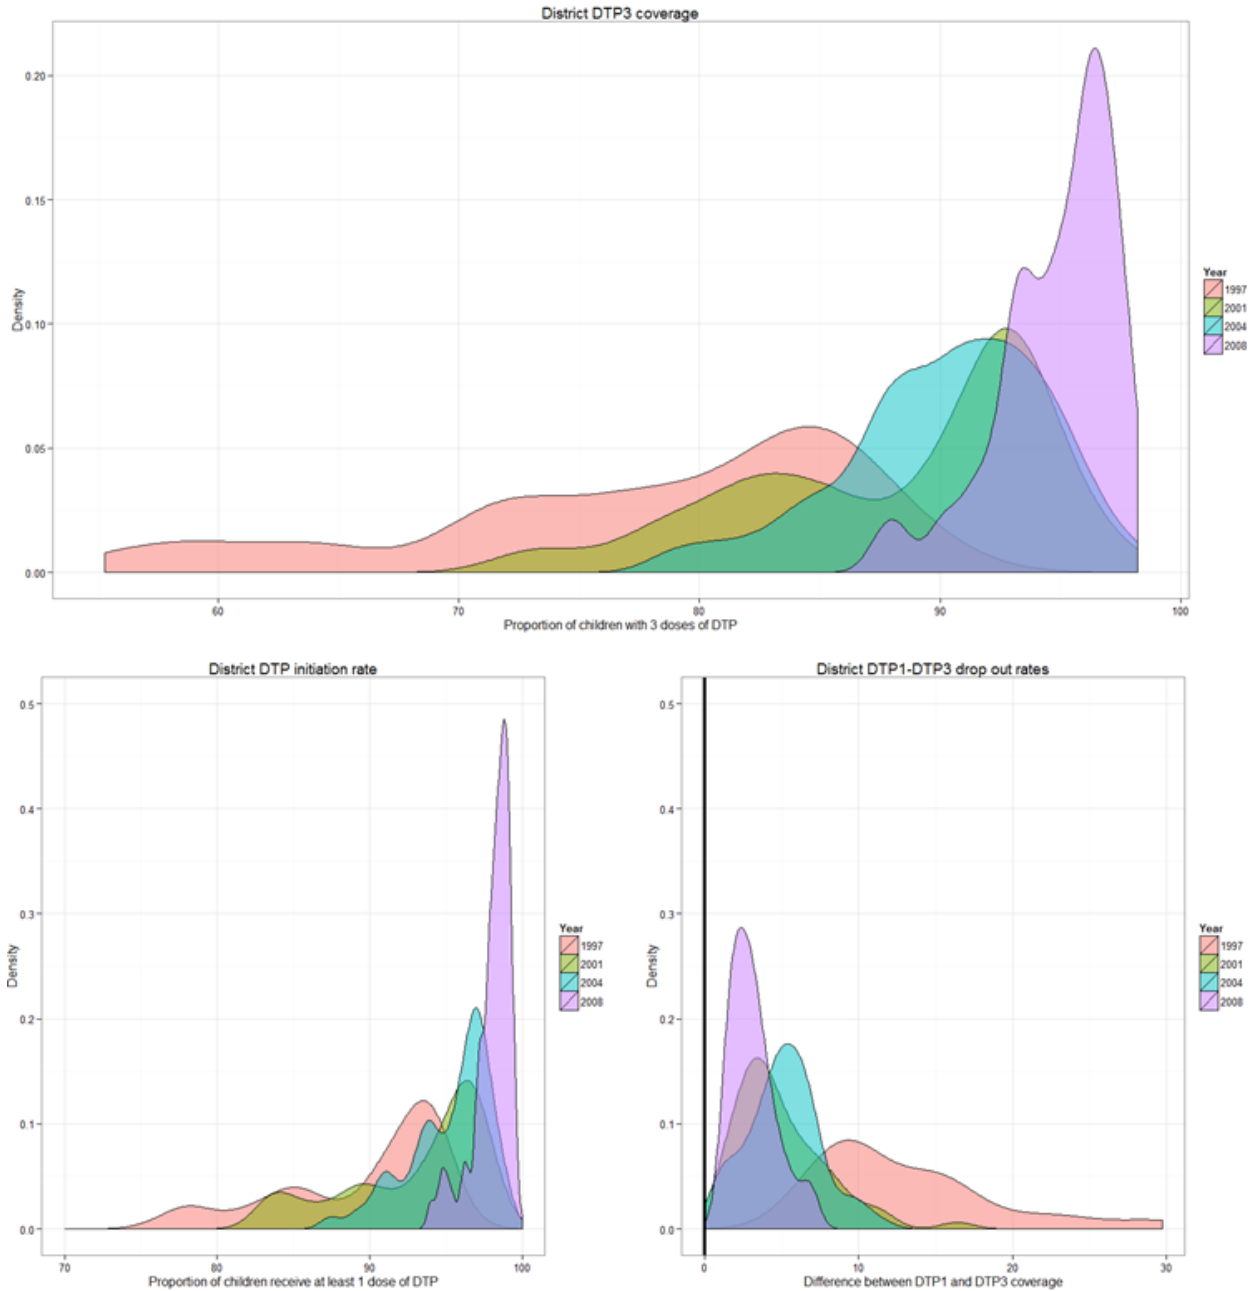

Table 2 lists the range and standard deviation of vaccination coverage in 1995 and 2013 across districts for the five main outcomes. The range is useful to seeing the total spread; the standard deviation better describes the majority of the variation. As the shrinking ranges and standard deviations suggest, equality in vaccination coverage across time is improving – the standard deviation for DTP3 coverage has decreased almost three fold since 1995. However, it is notably that the change in the standard deviation over time is not even across antigens – in 2013, the standard deviation for measles was 1.5 times higher than the standard deviation for BCG, suggesting uneven service delivery by antigen.

**Table 2: Range and Standard Deviation in District coverage, 1995-2013, Bangladesh**

<i>Vaccination</i>	<i>Range 1995</i>	<i>Standard Deviation 1995 (95% uncertainty intervals)</i>	<i>Range 2013</i>	<i>Standard Deviation 2013(95% uncertainty intervals)</i>
<b>BCG</b>	25.1	7.1 (6.5-7.6)	8.5	3.9 (2.8-4.3)
<b>DTP3</b>	33.4	10.0 (8.4-11.0)	9.0	3.5 (2.8-4.3)
<b>OPV3</b>	26	9.1 (8.3-9.6)	12.3	4.2 (3.4-5.0)

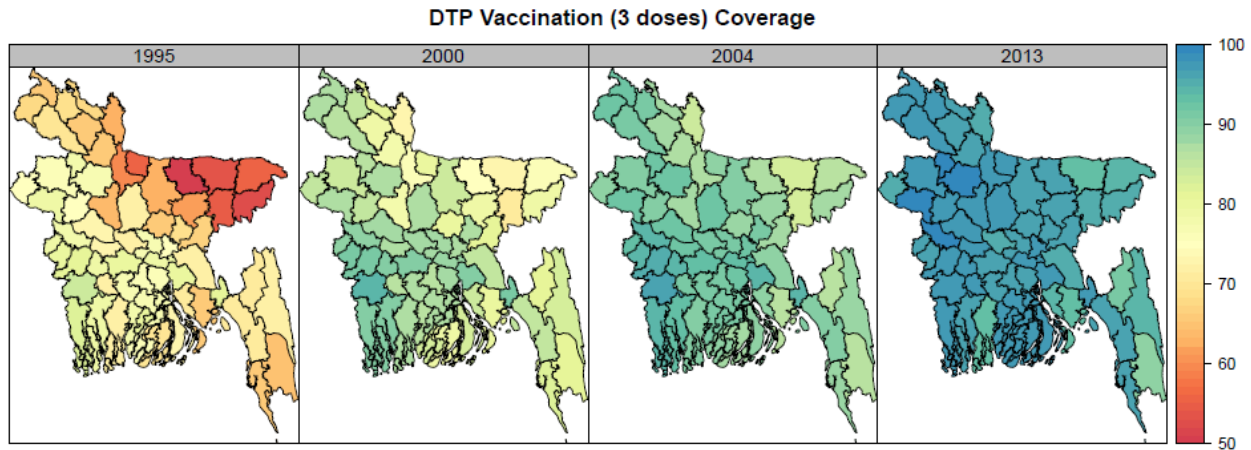

<b>Measles</b>	28.4	9.1 (8.3-9.6)	18.4	6.2 (5.5-7.0)
<b>Fully Vaccinated</b>	28.8	8.8 (7.6-9.9)	12.2	5.0 (4.3-5.7)

Just as absolute coverage across antigens has improved in Bangladesh, so too has the dropout rate for DTP1 and DTP3. The series of three graphs in Figure 4 suggest that the increasing DTP3 coverage over time can be attributed both to more children initiating the DTP series (increased proportion of children with at least one dose of DTP) and a decreasing dropout rate (decreased proportion of children who start but do not complete the DTP series). The left bottom panel show a more equitable distribution of initiation rates over time – although the mean initiation rate did not increase very much between 1997 and 2008, the standard deviation in initiation rates decreased quite dramatically. In 1997 the standard deviation of the initiation rate was 5.4% as compare to 1.2% in 2008. Although no districts have yet achieved perfect equality between initiation and completion of the DTP series, there has been continuous improvement over time as the density of districts with lower dropout rates increases and the tails of the distribution narrow. Between 1997 and 2008, the average dropout rate between DTP1 and DTP3 across districts decreased from 13.1% (SD: 5.8%) to 3.2% (SD: 1.5%).

**Figure 4: District DTP3 coverage against DTP initiation rate and DTP1-DTP3 dropout rate, 1997-2008**

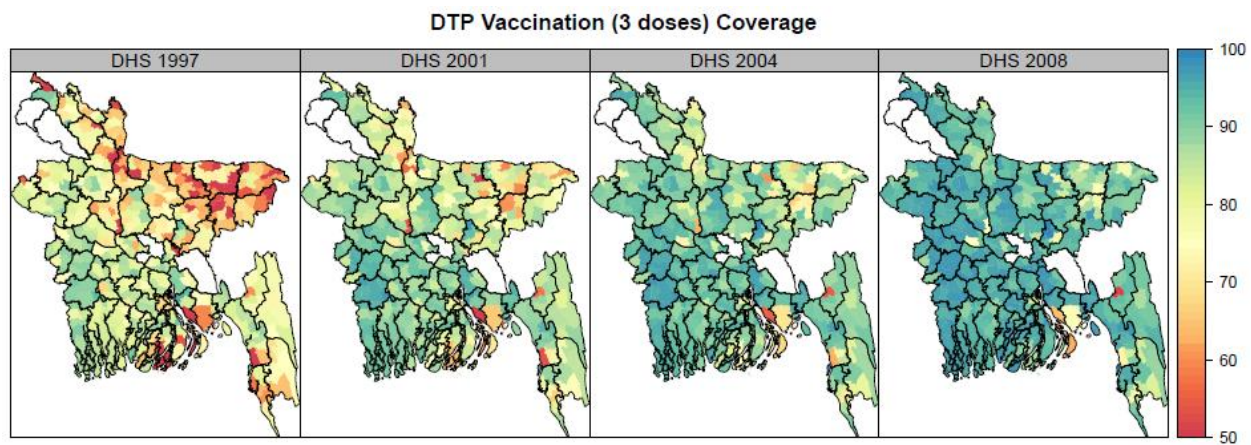

Figure 5 highlights the geographical pattern emblematic of vaccination coverage in Bangladesh. Although vaccination coverage has improved over time, geographical inequalities remain. Vaccination coverage is consistently lower in the eastern part of country in Sylhet and Chittagong divisions. These divisions are both hard-to-reach areas; Sylhet division is low-lying and prone to flooding a majority of the year, and Chittagong division is remote and mountainous. These attributes impact their health systems development and health care access.<sup>37</sup> The western part of the country, particularly Rajshahi and Khulna divisions have some of the highest vaccination rates.

**Figure 5: District DTP3 vaccination rates, 1995-2013, Bangladesh**

The smooth district pattern of vaccination coverage is attenuated when we move to the upazila level. Figure 6 illustrates the value of analysis at this level - visible here are intra-district geographical patterns and variability in vaccination coverage which are masked at the district level. In particular, Figure 6 reveals clustering of vaccination coverage across district boundaries in the Dhaka-Sylhet border region, and in the eastern part of the delta in Barisal and Chittagong divisions. Hotspots of low coverage within districts in the center of Dhaka division are also visible at the upazila level, as well as lower coverage across the border upazilas in the northern part of Rangpur division. Even in Rajshahi division, where average DTP3 vaccination coverage is 96.2% (77.5-99.3) at the division level, there are upazilas with coverage as low as 75.5% (59.4-86.2).

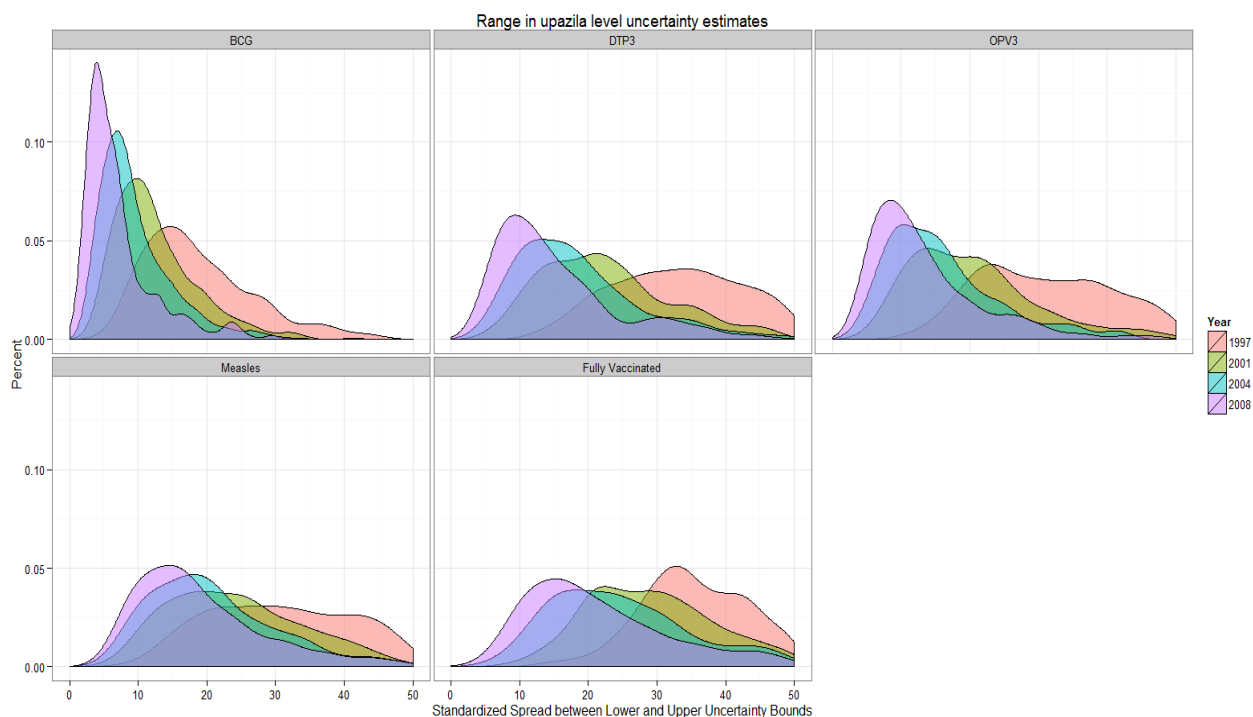

Chittagong division in particular displays tremendous variation by upazila. Although the division as a whole has some of the lowest vaccination coverage rates in the country, there were upazilas with coverage above 95% for DTP3 vaccination in 2008. DTP3 vaccination coverage in 2008 varied in Chittagong division from 51.8% (30.8-68.2) in Matiranga upazila, Khagrachhari district to 98.4% (94.8-99.6) in Chandpur upazila, Chandpur district, with a median coverage across upazilas of 94.2%. This spread in vaccination coverage across upazilas highlights the value of sub-district analysis, particularly when coverage rates do not follow district boundaries. The full series of upazila maps is available in the appendix.

**Figure 6: Upazila DTP3 vaccination rates, 1997-2008, Bangladesh**

Note: Upazilas with white indicate areas without population data available in the 2001 census; we could not rake these estimates to the higher levels of aggregation.

The uncertainty in the upazila estimation is highlighted in Figure 7, which displays the standardized spread in uncertainty across antigens over time. The spread in uncertainty shrinks over time as the number of upazilas sampled by the DHS increases, and as the sample sizes within each upazila grows. In the 1999-2000 DHS, the earliest survey with GPS coordinates recorded, 241 upazilas were sampled. This increased to 318 in the 2011-12 DHS; however this is still just 65% of total upazilas in the country. The more upazilas sampled by household surveys, and the larger the sample sizes in each upazila sampled, the more precise sub-district estimates can become.

**Figure 7: Range in upazila level uncertainty estimates across antigens, 1997-2008, Bangladesh**

Vaccination coverage in Mozambique has a more tempered story of success over the last twenty years. Coverage across the country has increased, although not consistently across space or by antigen. Coverage for OPV3 has increased the most of all antigens, from 48.5% (45.1-51.5) in 1994 to 74.3% (70.3-77.8), a rise of 25.8%. Measles and DTP3 coverage have increased by similar margins, 19.1% and 15.9%, respectively, resulting in national coverage estimates of 83.8% (79.7-86.9) for measles vaccination and 76.9% (73-80.6) for DTP3 vaccination in 2013. BCG coverage, which started at the highest level in 1994 by almost 15%, subsequently increased the least (8.5%) between 1994 and 2013 from 79.6% (76.9-82) to 88.1% (86.1-89.6). The rate of full vaccination coverage increased almost 37% from 29.8% (27.1-32.3) in 1994 to 66.5% (62-70.6) in 2013, suggesting improved health care delivery and health care access. Despite this growth, almost one-third of children in Mozambique in 2013 still had not received all routine childhood vaccinations.

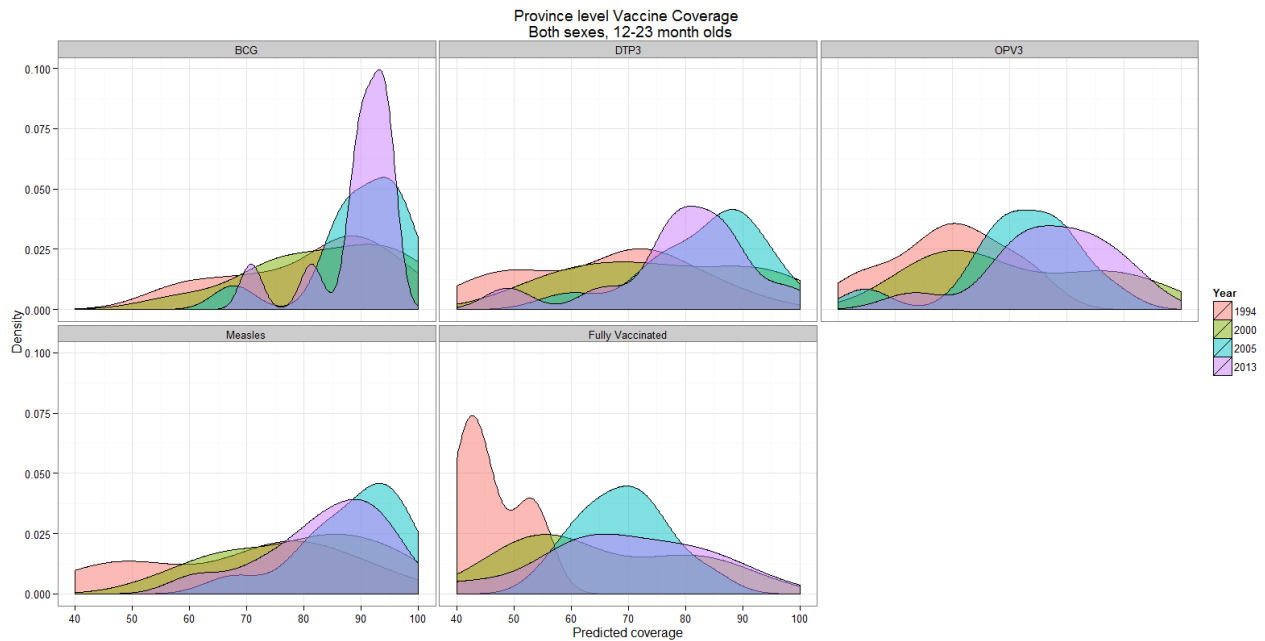

Table 3 reports national vaccination coverage across the five major outcomes and the absolute gain in coverage between 1994 and 2013.

**Table 3: National Coverage with uncertainty intervals, Mozambique**

<i>Antigen</i>	<i>1994</i>	<i>2000</i>	<i>2005</i>	<i>2013</i>	<i>Increase 1994- 2013</i>
<b><i>BCG</i></b>	79.6% (76.9-82)	82.8% (81.7-84.1)	88.7% (87.9-89.6)	88.1% (86.1-89.6)	8.5
<b><i>DTP3</i></b>	61% (58-64.6)	67.6% (66-69.1)	80.6% (78.9-82.1)	76.9% (73-80.6)	15.9
<b><i>OPV3</i></b>	48.5% (45.1-51.5)	61.4% (59.9-63.1)	67.1% (65-68.8)	74.3% (70.3-77.8)	25.8
<b><i>Measles</i></b>	64.7% (61.1-68)	76.3% (75-77.5)	86.7% (85.4-88.1)	83.8% (79.7-86.9)	19.1
<b><i>Fully Vaccinated</i></b>	29.8% (27.1-32.3)	54.9% (53.5-56.3)	59.7% (57.3-61.5)	66.5% (62-70.6)	36.7

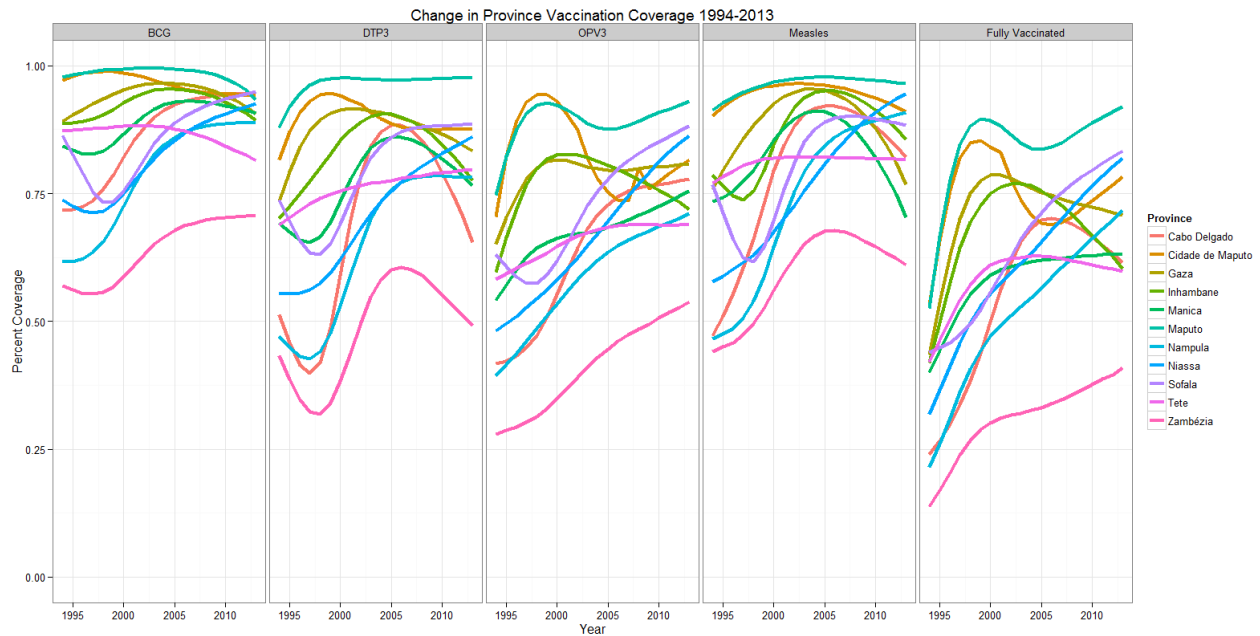

Figure 8 illustrates increasing trends in vaccination coverage rates over time in Mozambique, as well as the variability in coverage across antigens between 1994 and 2013. The time series plots of provincial vaccination coverage across the five major antigens can be found in the appendix. As the density of districts at higher levels of coverage has grown, the equality in vaccination rates for some antigens has improved, albeit to a somewhat small degree. The narrowing of the distribution in coverage is most pronounced for BCG vaccination – between 1994 and 2013 the range in BCG coverage across provinces shrunk 16.2 percent from 40.4% in 1994 to 24.2% in 2013. However, areas of low vaccination persist into 2013 as demonstrated by the bumps towards the left tail of the distribution. These are Zambézia province, which had a BCG coverage rate of 70.6% (63.7-76.1) in 2013, and Tete province where BCG coverage was 81.1% (73-87.1). Maputo province on the other side of the scale had a BCG vaccination rate of 97.6% (95.4% to 99%) in 2013.

Vaccination coverage has not become more equitable across all antigens in Mozambique. In particular, differences between provinces widened for DTP3 vaccination and full vaccination rates. In 1994, there was a 44 percentage point difference between DTP3 coverage in the highest performing province (Maputo: 87.6% (81.4-93)) and the lowest performing province (Zambézia: 43.6% (35.3-52.9)). In 2013, this gap widened to 48.1 percentage points, although absolute coverage increased in both provinces. Subsequently, the disparity between full vaccination coverage across provinces increased – the standard deviation across provinces in 2013 was 15% (12.9-16.9), up from 13.1% (11.2-14.4) in 1994. The greater equality in BCG vaccination over time as opposed to DTP3 could suggest improved early contact with the health system with greater barriers for sustaining contact.

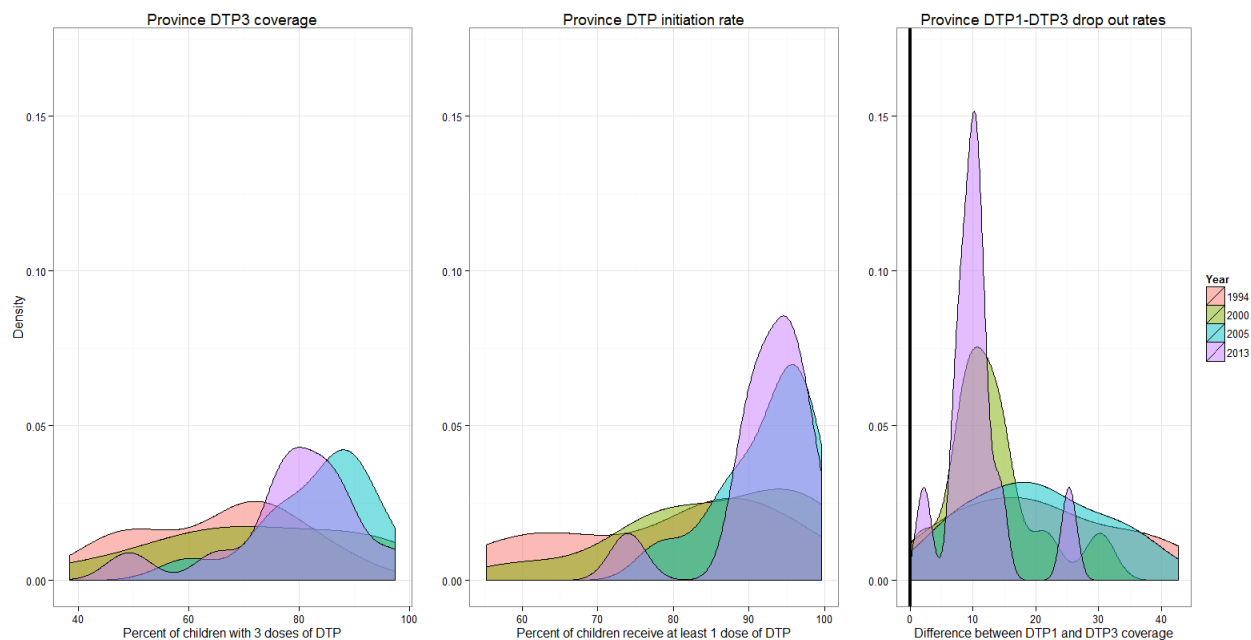

**Figure 8: Province level vaccination coverage, 1994-2013, Mozambique**

Figure 9 makes clear the differences in coverage by antigen and by province in Mozambique. Displayed is the time trend between 1994 and 2013 across the five major antigens. The slopes of the lines vary considerably across provinces by antigen (within 1 panel) and across antigens by province (between panels). Generally, the provinces are ranked in the same order across antigens. Manica and Gaza provinces have the highest coverage across antigens; Cabo Delgado and Zambézia, the lowest. Combined with the kernel density plots in Figure 8, this figure makes clear the differential improvement in coverage by antigen and by province, as well as across time. These different rates could suggest the possibility of differential availability, delivery mechanisms (routine vs. intensive campaigns) or demand for services by antigen. Additionally, it is notably that vaccination coverage is decreasing in some of the lower performing provinces in the most recent time period, suggesting the need to refocus additional on these lower performing areas.

**Figure 9: Absolute change in province vaccination coverage, 1994-2013, Mozambique**

The three panels in Figure 10 suggest that for those with access to the health care system, continuity of services received is increasing over time (right panel); additionally, more children are accessing the system to initiate the DTP vaccination series (middle panel). DTP3 coverage is a function both of the initiation rate and the dropout rate. In Mozambique it seems that although the mean DTP3 coverage rate has not increased much over time, there are more children starting the series and fewer children dropping out. There is also increased equality in the initiation and dropout rates. Between 1994 and 2013 the standard deviation for the initiation rate decreased from 14.5% to 6.7%; similarly the standard deviation for the dropout rate decreased from 12.9% to 5.7%. This means that the difference between the lowest and highest performers is decreasing over time.

**Figure 10: DTP3 coverage compared to DTP initiation and DTP1-DTP3 dropout rates, 1994-2013, Mozambique**

Moving to a district-view of vaccination coverage in Mozambique reveals a more nuanced story of success, missed opportunities, and areas for improvement. Table 4 displays the range across the districts for each antigen in 2009 as well as the standard deviation with 98% uncertainty intervals. Variation by district is much larger than by provinces, with the standard deviation above 10% for each antigen.

**Table 4: District variation in vaccination coverage, 2009, Mozambique**

<i>Vaccination</i>	<i>Range across districts</i>	<i>Standard Deviation (95% uncertainty intervals)</i>
<b><i>BCG</i></b>	51.2	10.5 (9.9 - 11.1)
<b><i>DTP3</i></b>	54.1	13 (11.9 - 14.5)
<b><i>OPV3</i></b>	51.3	12.3 (11.1 - 13.2)
<b><i>Measles</i></b>	46.3	11.3 (10.3 - 12.4)
<b><i>Fully Vaccinated</i></b>	68.8	16 (14.1 - 19.5)

Figure 11 shows the geographical patterning to this district variability, highlighting clustering of vaccination rates and hotspots of high and low coverage which are masked by province level estimation. The middle of the country, which includes Zambézia and Tete provinces, has the lowest coverage rates across antigens. The panel maps in Figure 11 are all on the same scale, highlighting the disparities between BCG vaccination coverage and fully vaccination both across the country as a whole and by province. Visible at the district level are also areas of intra-province similarity, where districts across provinces share similar vaccination coverage rates. For example, there is a cluster of districts along the Cabo Delgado – Zambézia border with very similar DTP3 and full vaccination coverage rates. Similarly, districts in northern Sofala and northern Manica along the border with Tete and Zambézia have similar coverage levels with districts in these two latter provinces. Specifically, full vaccination coverage

Chemba district in Sofala lags 36.2% percentage points behind its province average and is within 4 percentage points of the Zambézia provincial estimate, suggesting shared characteristics. Other examples include Massinga and Homoine districts in Inhambane province, which are 8.4% and 17%, respectively, behind the province average for full vaccination coverage.

The district analysis also shows positive deviants. Maganja da Costa, Namacura, and Nicoadala are three districts in Zambézia which out-perform the rest of the district; they are clustered along the central section of the eastern Zambézia coast, suggesting some geographical rationale to their deviance.

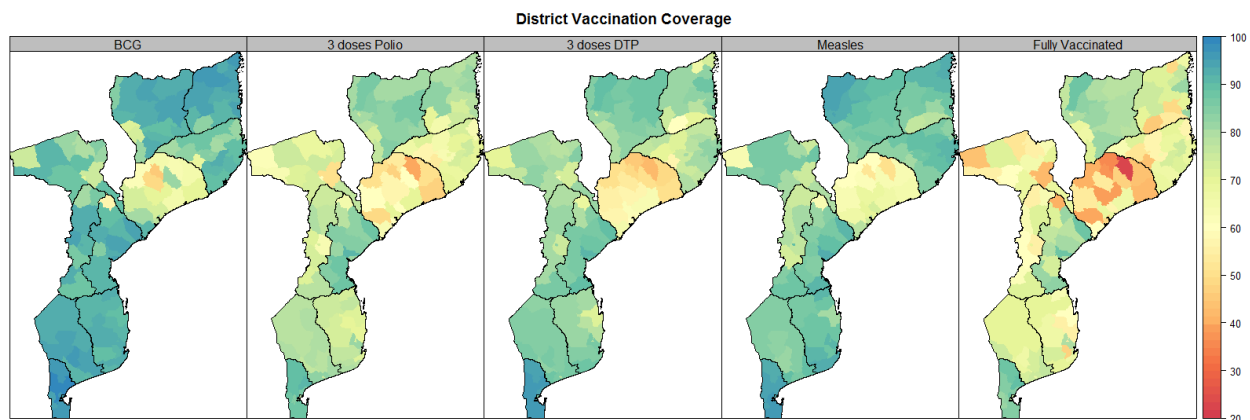

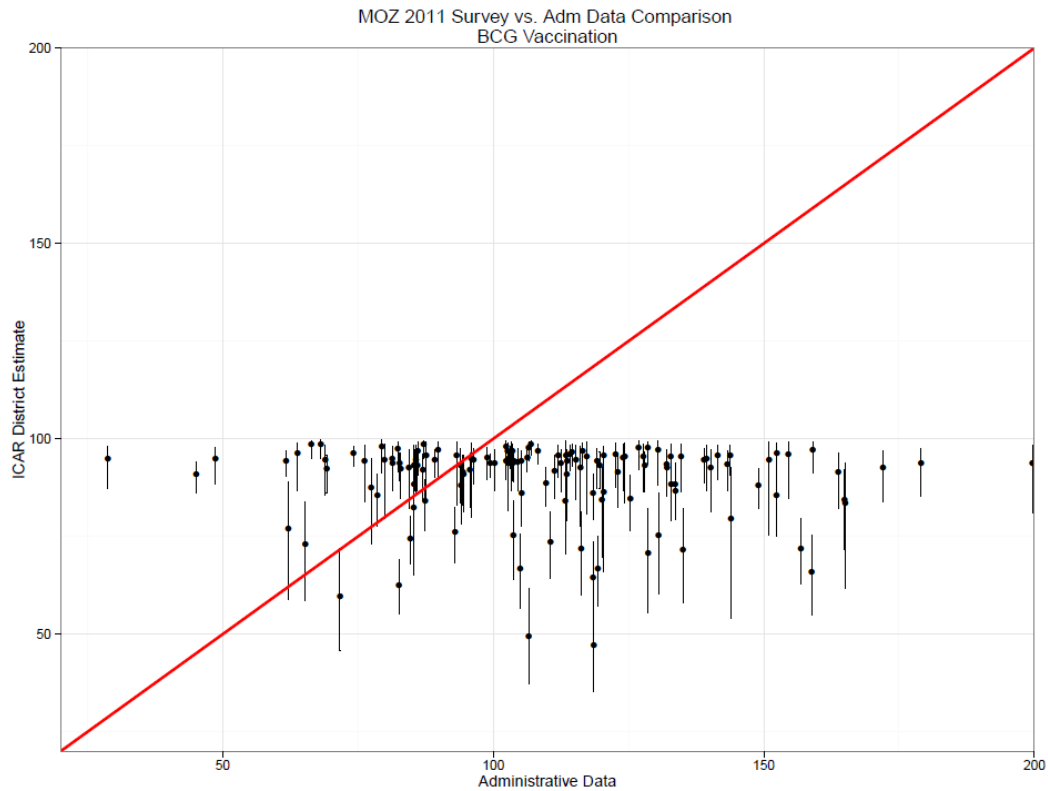

Figure 11: District vaccination coverage, 2009, Mozambique

Figure 12 is another way of visualizing the variation by districts while also capturing the uncertainty in the estimates. Highlighted here are the province estimates plotted against the district estimates for Zambézia for the five antigens. The height of the vertical uncertainty intervals for each district much exceeds the vertical width of the province uncertainty, a consequence of dramatically smaller size samples and limited data availability. Note that overlapping uncertainty intervals does not mean the district is not statistically different from the province mean. In fact, across antigens, there are at least 20 districts where vaccination coverage is statistically significantly different, either positively or negatively, from the province mean. There are 42 districts where BCG vaccination statistically differs from the province estimate, 23 instances of this for measles vaccination, and 20 each for DTP3, OPV3, and full vaccination. This amount of significant variability makes clear the value of district analysis in Mozambique – within a province, there is large variation in performance which needs investigating. Knowing which districts are positive deviants, and which are underperforming can help lead to target interventions to apply the lessons from the former to barriers and constraints in the latter.

**Figure 12: District vaccination coverage as compared to province estimates, 2009, Mozambique**

The more data available at lower administrative levels, the more precise and accurate local-level estimates can become and the more powerful the results will be for policy makers and health professionals. To that end, existing health information systems can be a valuable resource to strengthen survey-based estimates. However, in many low-and middle-income countries, concerns remain about the quality of administrative data, limiting their use in generating estimates for policy decision making.<sup>23</sup> In Mozambique in particular, chronic resource shortages, vertical funding from donors, and management challenges all limit service coverage and quality, restricting the usability of the health information system.<sup>38</sup> A review of the reporting system, Módulo Básico (MB), for childhood vaccination coverage from 2000-2013 undertaken for this paper revealed vaccine coverage greater than 100% in over half of districts for all antigens throughout this time period (Figure 13). The MB system was revamped in 2007 and again in 2013 as the government continues to decentralize the health system. Despite the infusion of support for the system and additional health worker trainings, in 2013, 80 of Mozambique’s 148 districts reported coverage greater than 100% for almost all childhood antigens. This suggests unreliability in the administrative data in Mozambique, which could be introduced as a result of incorrect or incomplete reporting at health centres, as data is collated and transferred up the administrative levels or as a result of incomplete or over-reporting from private or NGO sectors, and intensive vaccination campaigns. Errors might also arise due to outdated censuses, incomplete population registries or inaccurate population projections.

**Figure 13: District vaccination coverage - survey estimates vs. administrative data, Mozambique**

In Bangladesh, we did not have access to the health information system, although upazila and district level reports are collated monthly throughout the country. Doing a similar comparison between survey and administrative data in Bangladesh would improve our understanding of existing data resources at the upazila level and illustrate potential attributes of both data systems to be improved upon. Strengthening the quality of health information systems could contribute to more timely vaccination coverage estimates at local levels given the lag between household survey collection and report release common to surveys such as the DHS and CES. Additionally, health information systems are representative at the lowest administrative levels as opposed to household surveys which tend to be representative only down to the second administrative level in most countries.

### Discussion

This study is, to our knowledge, the first to estimate vaccination coverage at the upazila level over time in Bangladesh. It is also the first to our knowledge to produce estimates for all 148 districts in Mozambique. Our results illustrate a story of success in Bangladesh over the last twenty five years as more and more upazilas increased vaccination coverage across antigens and narrowed disparities in vaccination rates. In Bangladesh in 2008, almost all upazilas had reached the goal laid out by UNICEF in 1984 for achieving “Universal Childhood Immunization (UCI) by 1990” initiative, for BCG, OPV3 and DTP3 vaccinations, where success was defined as 80% immunization coverage.<sup>5</sup> In fact, as early as 1997, 248 of the 426 upazilas we produced results for were statistically likely to have achieved the 80% target for BCG coverage. Achievement in 2008 was lower for measles, with 60.1% of upazilas in 2008 statistically likely to have achieved the 80% target. Still, this represents a growth of 204 upazilas since 1997 which have achieved the 80% target for measles.

Among these successes, remain missed opportunities to vaccinate children who most need these services. Gaps in coverage in Bangladesh and Mozambique are concentrated among the most vulnerable – the poorest and least educated.<sup>19,27</sup> Almost ten years after both countries launched their RED campaigns, the lowest performing upazilas remain concentrated in two main sections of the country – Sylhet and Dhaka divisions, and the delta region in Barisal and Chittagong divisions. Low coverage in Sylhet and Chittagong is not limited to immunization; the divisions lag behind in other markers of development including family planning acceptance, education level, and nutritional status.<sup>39</sup> Explanations for these low rates include the geography and ecology of the regions, poor staff-population ratios, lower density of NGO programs, and a more conservative culture leading to fewer uptakes in health and education interventions.<sup>2</sup> It seems that some of these characteristics may be shared across division boundaries given the upazila clustering in coverage rates with Dhaka, and Barisal divisions, respectively. Given these known disparities and potential explanatory factors, policy makers can take a targeted approach to improving vaccination coverage in the lowest performing upazilas.

Mozambique's story of vaccination coverage in the last twenty years differs rather substantially from that in Bangladesh. Vaccination rates have increased throughout the country, although progress has not been consistent across time or across antigens. In fact, disparities between provinces have widened for certain antigens, notably DTP3 and full vaccination coverage. Progress towards the UCI goal is still to be achieved for all antigens – 71.6% of districts in 2010 had greater than 80% BCG vaccination but only 29.7% had achieved this threshold for measles. Fewer still had reached 80% coverage for DTP3 and OPV3 – 16.2% and 2.4% respectively. Vaccination coverage for OPV3 remains below 70% in three-quarters of districts in Mozambique. Further, geographical disparities have not shifted in the last twenty years – provinces with low coverage in 1995 remained so in 2013. Importantly, the district level analysis reveals districts within high-performing provinces that lag far behind the provincial average. This warrants a deeper look at each province in Mozambique as health officials continue to improve health service delivery. Attention should particularly be paid to districts in Tete, Zambézia, and Cabo Delgado.

Comparing our results with other reported estimates gives confidence to our modeling approach. The direct estimates reported by the DHS in both countries fall within our uncertainty intervals across the time period. Additionally, our district results in Bangladesh align with the published CES reports.<sup>15,42-44</sup> Our approach has the advantage over single survey estimates of drawing strength across data sources, time and space. Employing a geospatial model allows us to make reasonable predictions for areas under-sampled by household surveys by drawing upon information from geographical and time-based neighbors. This is particularly valuable at the upazila level in Bangladesh where in any given DHS survey only 49 to 65% of upazilas are sampled. However, it should be noted that the ICAR models used here are approximation to the posterior distribution. Further, the ICAR model is only appropriate for strong spatial correlations among neighbors. Given that there are only eleven provinces in Mozambique, a model relying so heavily on spatial variation may not be the most appropriate choice for this administrative level. Further, we subjectively chose the number of knots in the spline component of the model for districts in Bangladesh and provinces in Mozambique; a proper model selection process may find a different number of knots and/or different placement of these knots to be more appropriate. This may also be related to the downtrends seen in certain areas in the projection period, 2011-2013.

Our estimates for Mozambican districts and Bangladeshi upazilas are fairly imprecise, as reflected by the large uncertainty intervals associated with each vaccination coverage rate. The wide degree of uncertainty in our estimates can be a motivating factor for public health officials and policymakers to focus on lower administrative levels for intervention improvement and targeting. Stating that measles vaccination coverage in 2008 in Narsingdi upazila in Dhaka, for example, could vary from 30% to 83% is useful for galvanizing efforts to design more surveys at the upazila level and improve health information system quality to strengthen our understanding of local level health. It should also be impetus to investigate in more detail the health situation in these areas.

Data availability limited our district analysis in Mozambique to one year. As more surveys collect geolocated data, district time trends will become possible, enriching the local health landscape. Similarly in Bangladesh, poor data codebooks limited our analysis to DHS sources. The version of the 2005 CES we received from the GAVI Full Country Evaluation partners at icddr,b included a variable for upazila but came without a codebook. The CES is district-representative and has 210 children 12-23 months sampled in each district. Obtaining a more complete dataset as well as other years of the CES with upazila identification will greatly improve the precision of these results.

In addition to limited data availability at the lower administrative levels, there are also limitations introduced by the sampling design of the data sources we used. The DHS survey, which employed a cluster sampling design, may not be representative at the district level, although we have used this source to make estimates at the district level in both countries, and at the sub-district level in Bangladesh. Our results should thus be interpreted with caution. Limited sample sizes at these lower geographical units also contribute to larger uncertainty. In Mozambique, uncertainty is largest in Cabo Delgado province in part because it has the largest percentage of districts (4 of 17) not sampled by the 2011 DHS. Maputo and Nampula provinces also carry large uncertainty in their district estimates due to median sample sizes per district of less than ten children. In Bangladesh, the number of children per upazila ranges from 2 to 277 with a median of 20 across the time period. These small sample sizes should act as a call to action to conduct surveys which are more robust at lower administrative levels, and for the development of a validation framework to strengthen the validity of our results.

Timely, high-quality measurements of vaccination coverage are essential to support sound decisions about progress and investments in children's health. At a time of increased funding opportunities for vaccination services, it is critical to improve our understanding of the variability in EPI system performance such that health systems strengthening initiatives can strategically target poor performing areas and maximize the new financial inputs. Action should be taken to continue improving health information at lower geographical areas, both through household surveys and administrative data. As we have illustrated here, such analysis is already possible in certain settings but remains highly uncertain. Despite the uncertainty in the point estimates, we believe the geographic patterns in our results can be used as a resource for further investigation of the health burden and health system performance in both low and high performing areas – what successes can be translated to low performing areas and what barriers can be addressed to increase vaccination coverage in lagging districts and upazilas? Further, our results can be used to target data collection efforts in specific areas.

Currently, there is little evidence on effective approaches to build capacity for using health data for routine decision making.<sup>45</sup> We are hopeful that local level health information, as illustrated in this analysis, can be part of the solution to motivate policy makers and public health officials to focus efforts on the most underserved populations and the last areas with low childhood vaccination coverage.
